©IPCC 2007: WG1-AR4

*Based on current understanding, only the collapse of marine-based sectors of the Antarctic ice sheet, if initiated, could cause global mean sea level to rise substantially above the likely range during the 21st century....IPCC AR5, 2013*

## Still open questions:

When did the Arctic Ocean begin having its modern configuration?

When did the Fram Strait and bering Strait fully open?

What's the origin of the Arctic Ocean ridges?

O. Engen et al. / Tectonophysics 450 (2008) 51–69

55

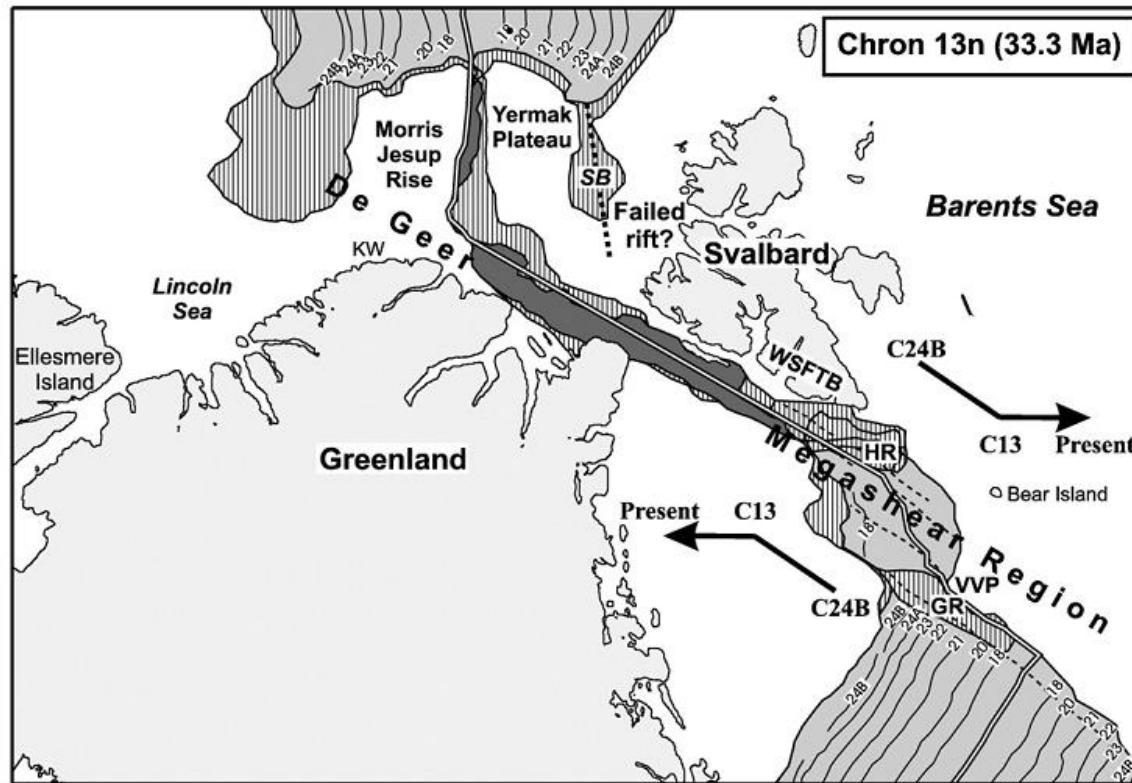

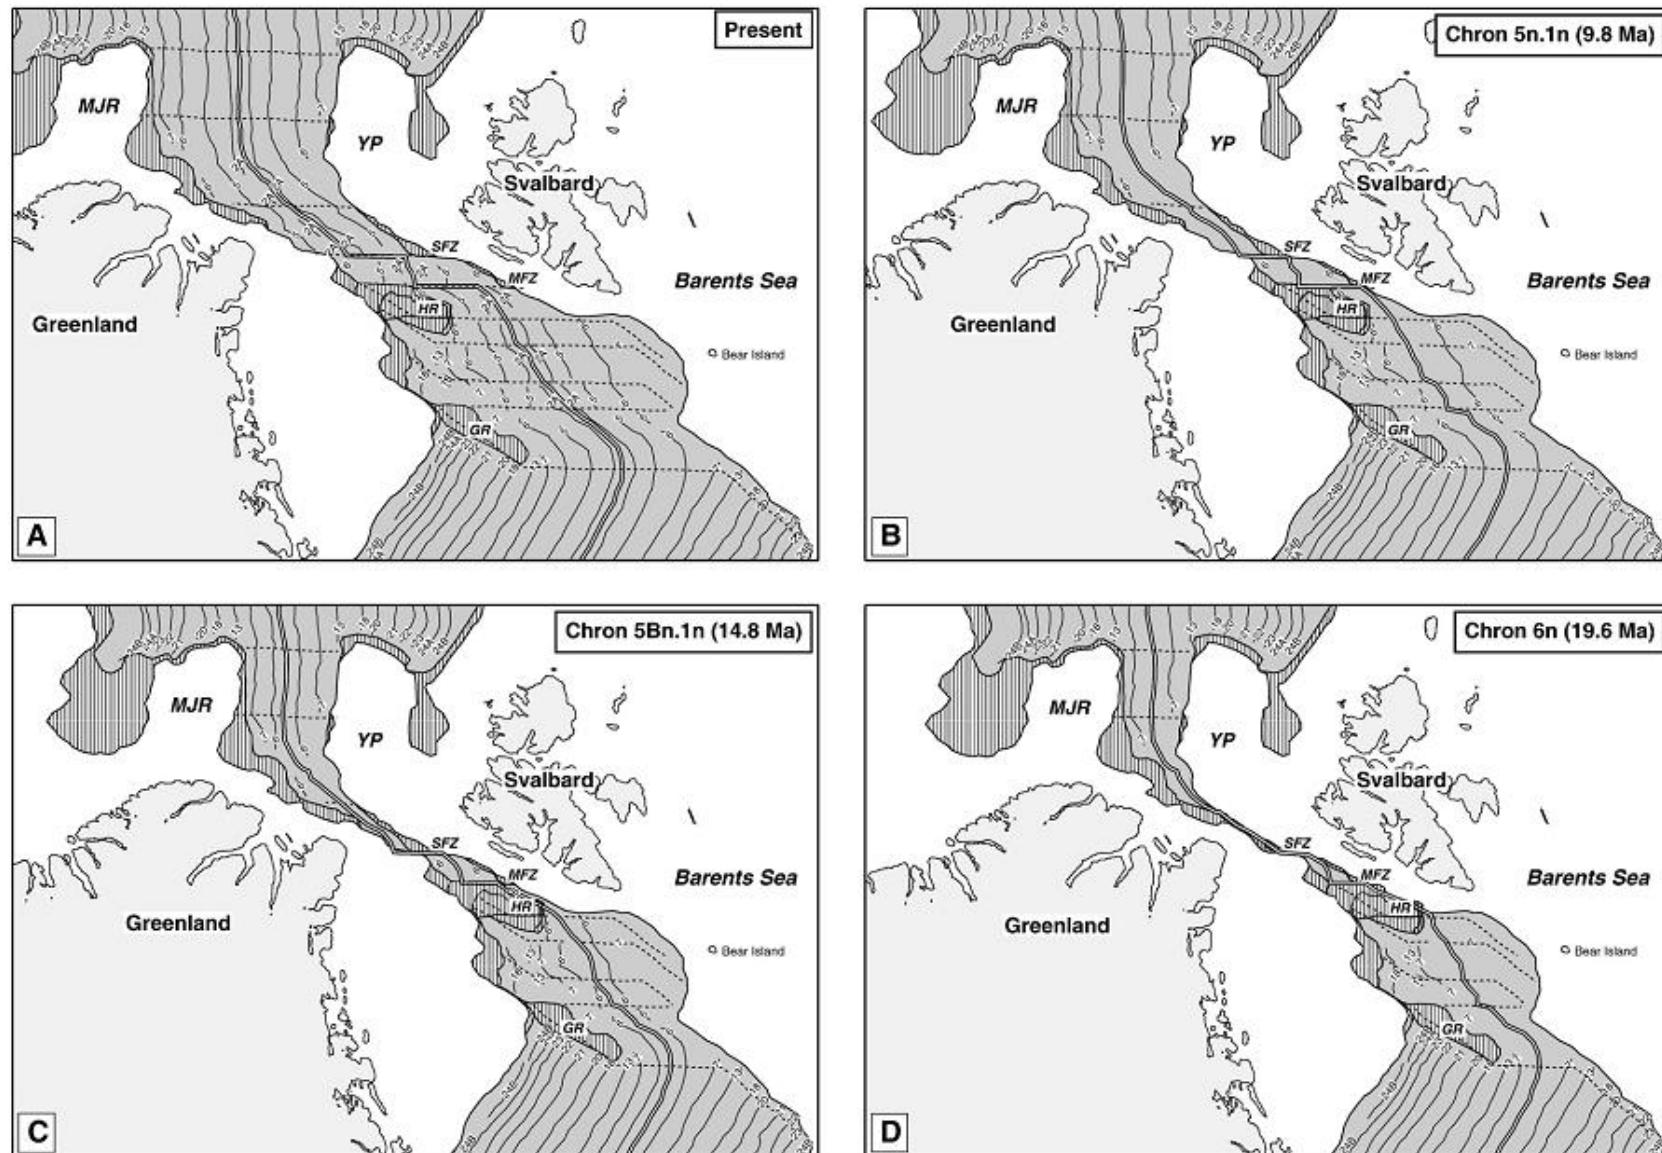

Fig. 4. Plate tectonic reconstruction of the Fram Strait region to Chron 13 times (earliest Oligocene), when relative plate motion between Greenland and Eurasia changed from right-lateral shear to oblique divergence (arrows). Area of crustal overlap (dark grey) indicates crustal stretching and thinning prior to breakup of the Lena Trough. The Sophia Basin (SB) may be a failed Eocene attempt to connect the Eurasia Basin and the Norwegian–Greenland Sea and might have facilitated early water exchange. WSFTB, West Spitsbergen Fold and Thrust Belt; other abbreviations as in Figs. 1 and 2.

O. Engen et al. / Tectonophysics 450 (2008) 51–69

Fig. 12. Plate tectonic reconstruction of the Fram Strait gateway. Eurasia is kept fixed and Greenland and North America rotated using the poles in Table 1. Oceanic crust is shaded and magnetic seafloor spreading anomalies shown as annotated bold lines. COT and uncertain crustal provinces hachured as in Fig. 2. Flowlines of relative plate motion shown by dashed lines. Reconstructions indicate (A) present-day Lena Trough; (B) Development of first well developed seafloor spreading anomalies during late Miocene times (~10 Ma); (C) Formation of an initial, narrow oceanic corridor during early Miocene times (20–15 Ma); and (D) closure between Svalbard and NE Greenland prior to early Miocene times (~20 Ma).

L'Italia (Prof. D. Rio Univ. Padova, micropaleontologo) ha partecipato all'unica perforazione profonda effettuata nello Oceano Artico dall'Integrated Ocean Drilling Program, il leg 301 IODP ACEX del 2004.

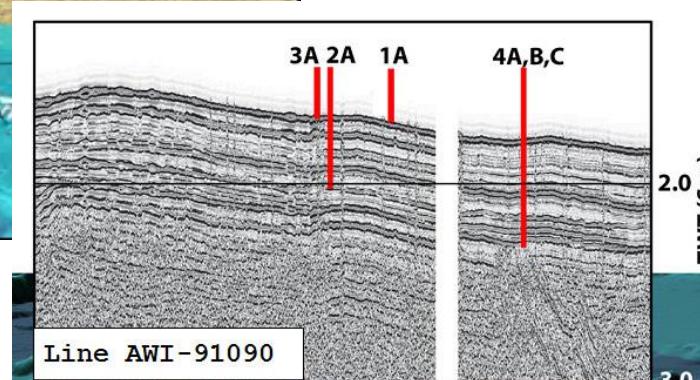

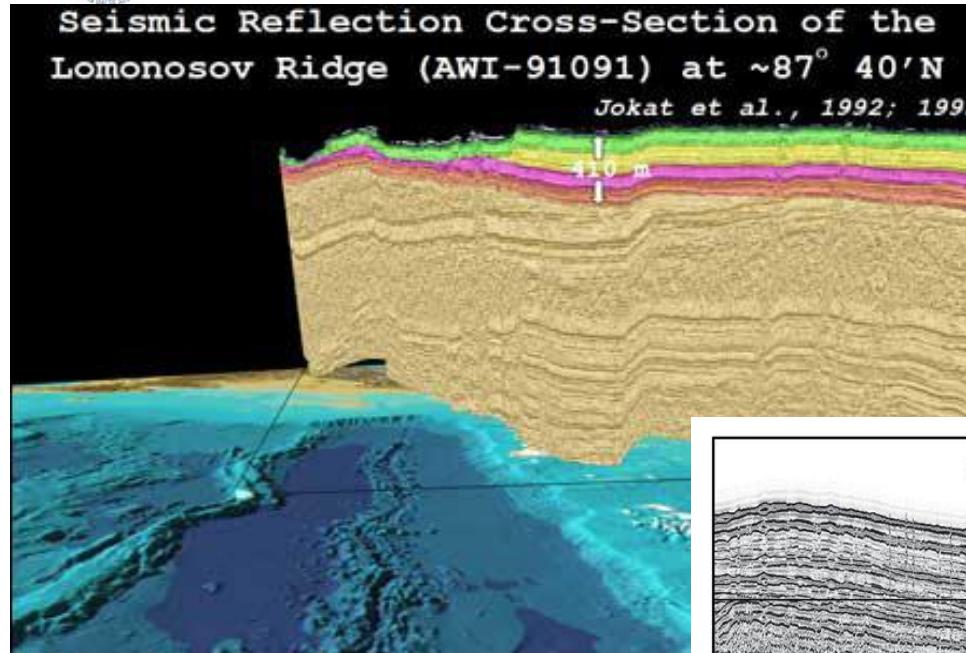

Durante tale leg sono stati prelevati 400 m circa di sedimenti sul Lomonosov ridge

La perforazione ha rivelato che le glaciazioni sono più antiche di quanto si era precedentemente stimato: ci sono IRD (Ice rafted debris) trasportati da icebergs e/o sea ice fino al centro dell'Artico e rilasciati in sedimenti di 17 milioni di anni. Precedentemente erano stati documentati solo in sedimenti di 6-10 Ma

**Vidar Viking could keep its position for max. 9 days**

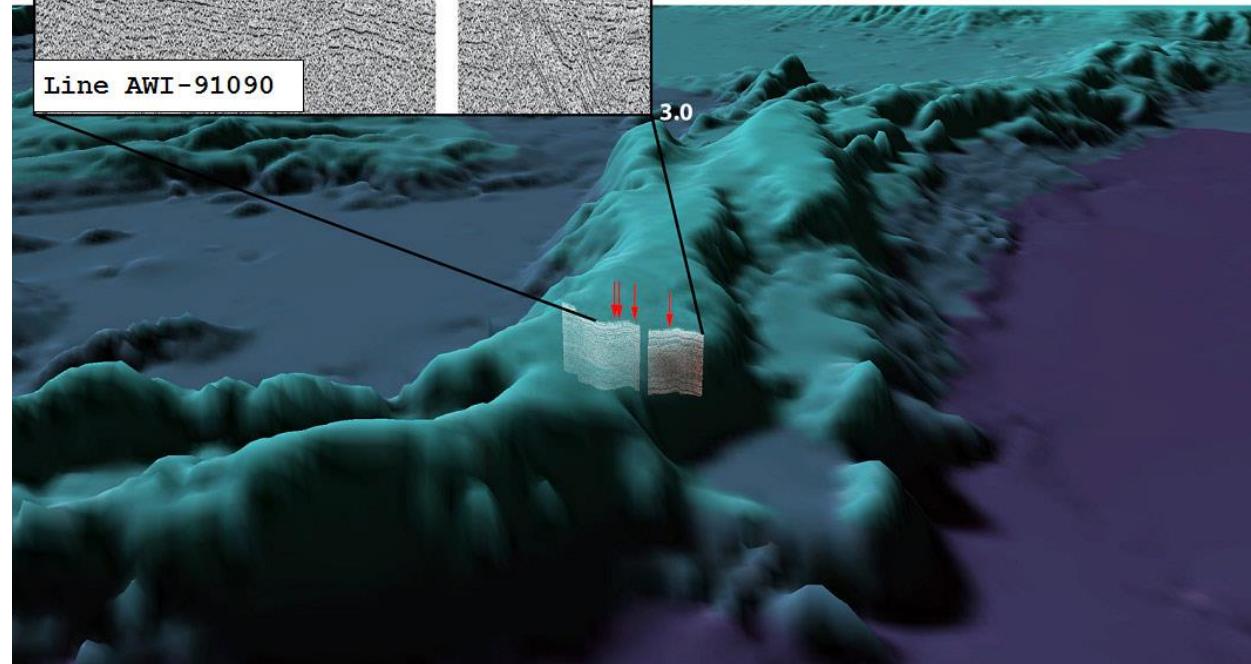

**Terminal Depths:**

Site M0001: —

Site M0002: 272.7 m

Site M0003: 15.0 m

Site M0004: 427.9 m

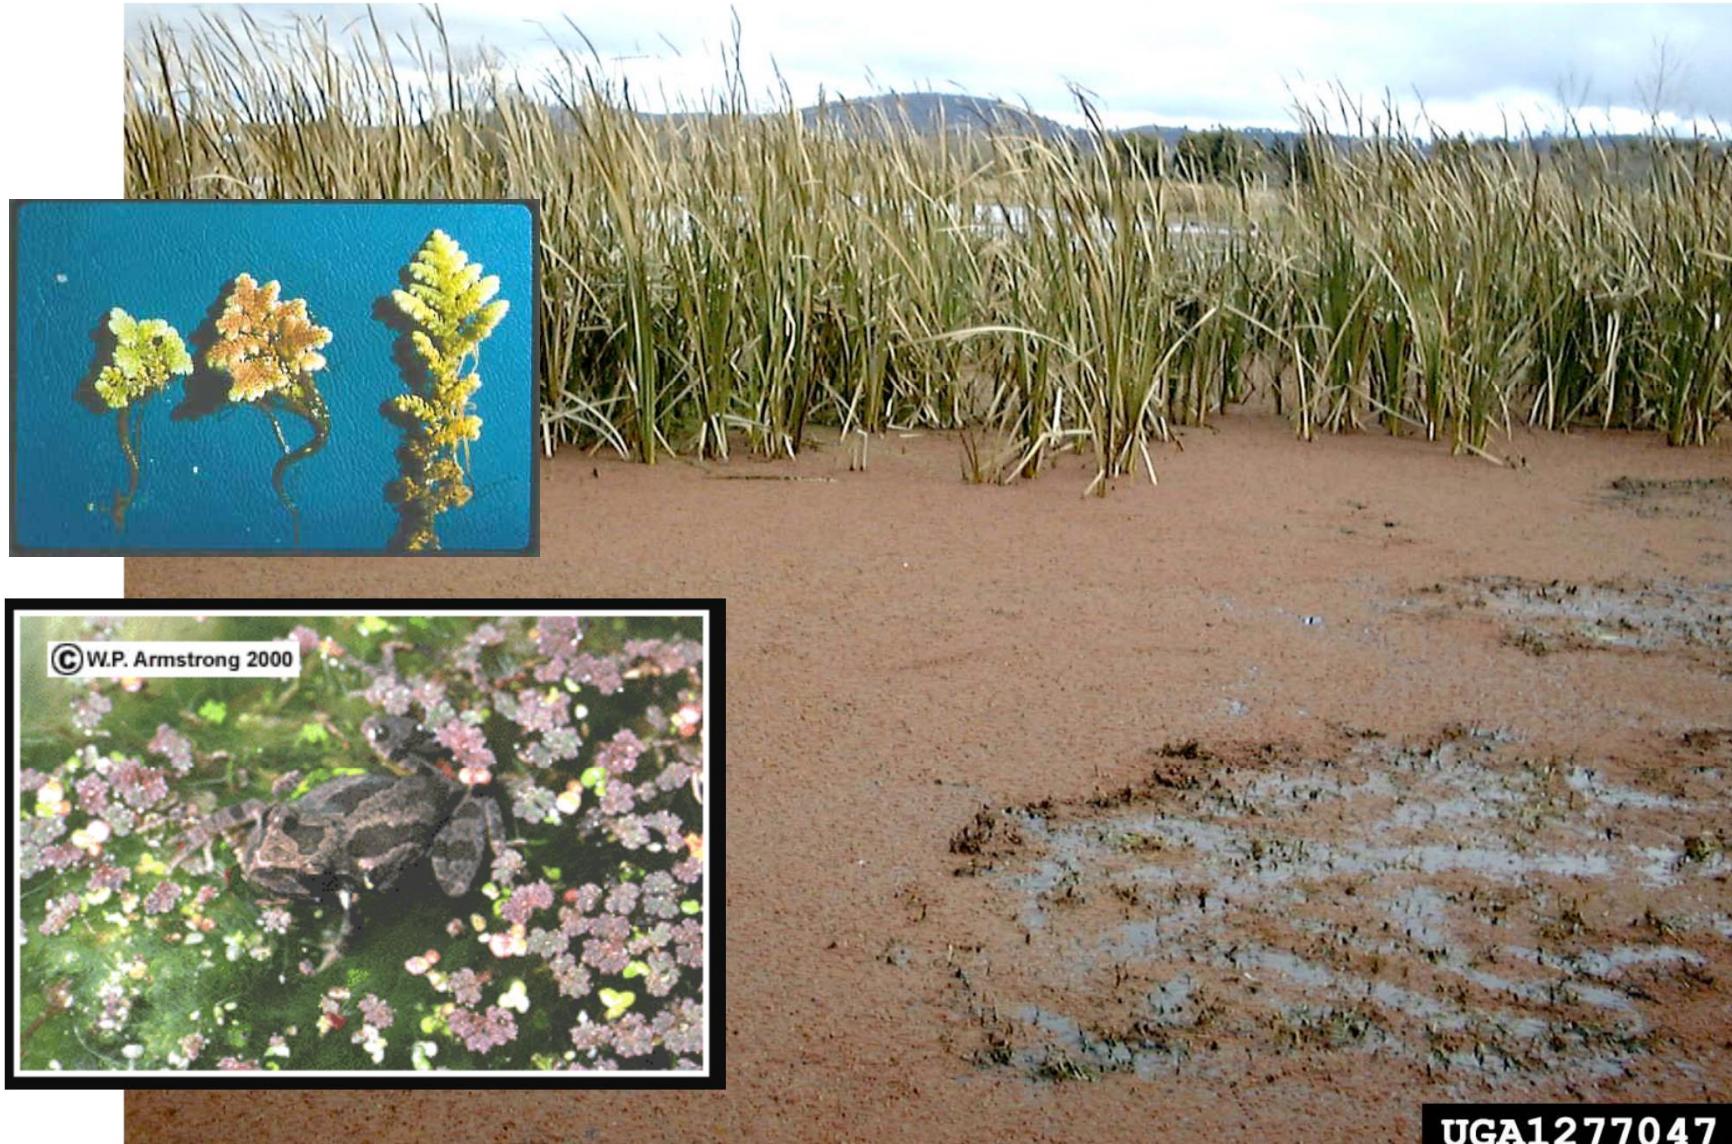

## IODP leg 302 in the Arctic Ocean (2004)

Co-chiefs: Backman, J., Moran, K., Evans, D.,

- “ Provided the timing of the deep. water connection to the North Atlantic Ocean of the Arctic Ocean: a key driver of the deep. water formation in the North Atlantic and Arctic Oceans, which in turn is a key driver of global climate.
- “ Confirmed that the Lomonosov Ridge is constructed of continental crust, genetically linked to the Barents Shelf.
- “ Revealed that the Cenozoic cooling in the Arctic occurred 17 Ma and possibly of 46 Ma ago, synchronously with that in the Antarctic, contrary to previous hypotheses.

Condizioni ambientali tipiche degli attuali regimi tropicali 55 Milioni di anni fa, con scarsa ventilazione, acqua dolce e condizioni anossiche (Arctic pond) intorno a 48.5 milioni di anni fa (rocce madri di idrocarburi)

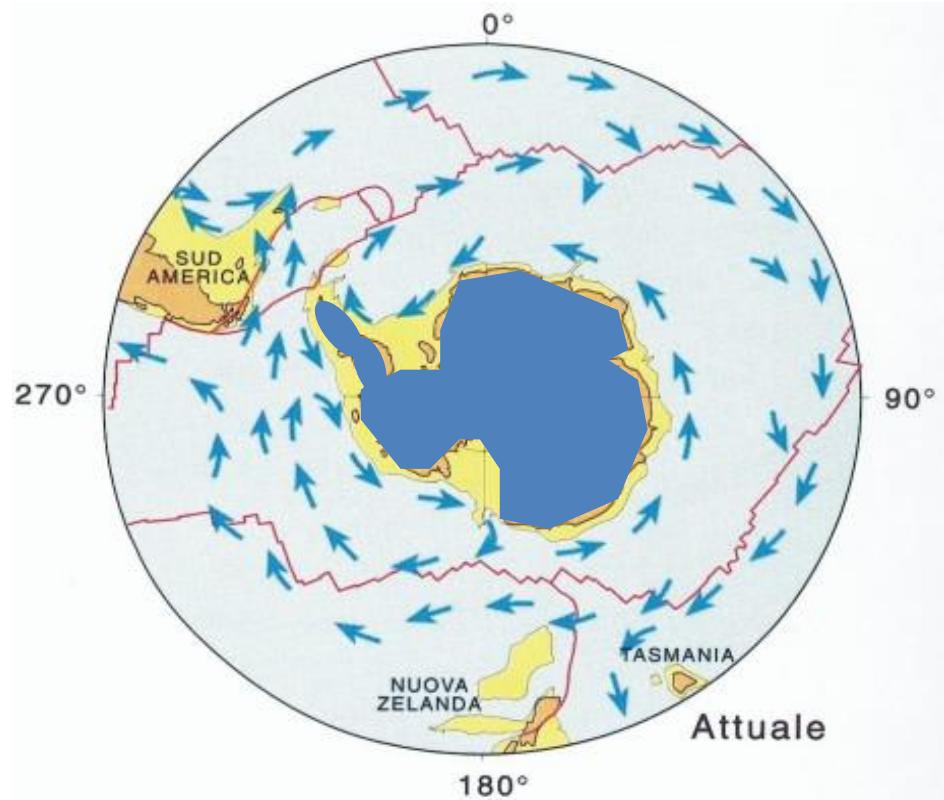

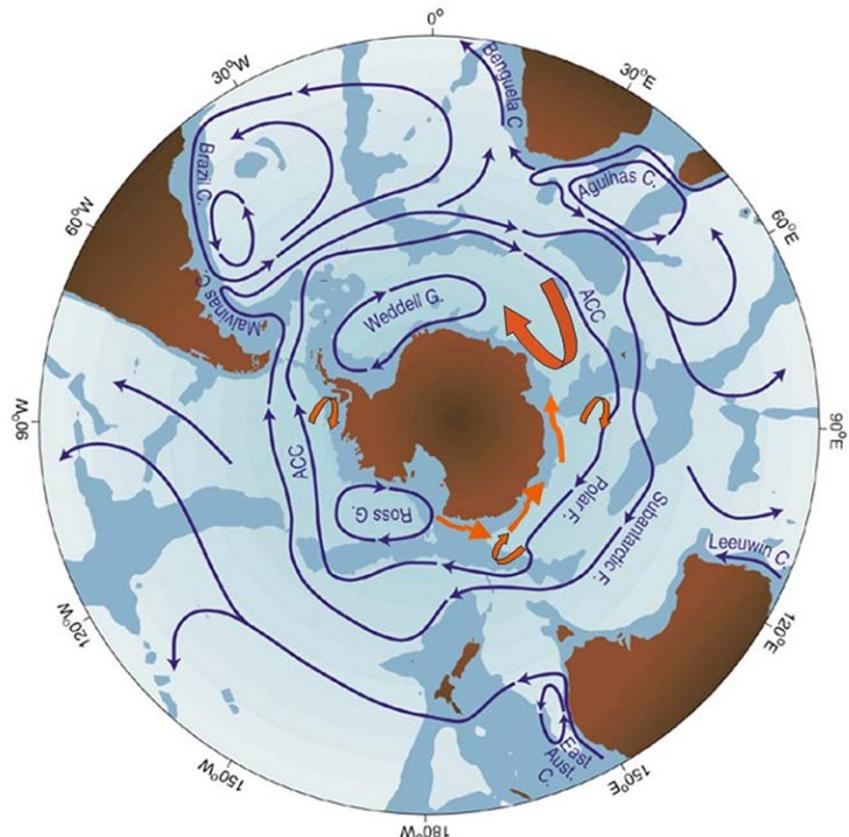

ACC transport of 100-150 Sverdrups ( $1 \text{ Sv} = 10^6 \text{ m}^3 \text{ s}^{-1}$ ).

Mean ACC temperature ranges from -1 to 5°C, depending on the time of year and location. The mean surface salinity decreases poleward, in general, from 34.9 at 35°S to 34.7 at 65°S.

The ACC extends from the sea surface to depths of 2000-4000 m and can be as wide as 2000 km. ACC flows eastward at  $20 \text{ cm s}^{-1}$  in regions between the fronts, driven by strong westerly winds. The average wind speed between 40°S and 60°S is 15 to 24 knots with strongest winds typically between 45°S and 55°S.

## Ice velocity and ice mass loss/gain

Rignot et al. (2007)

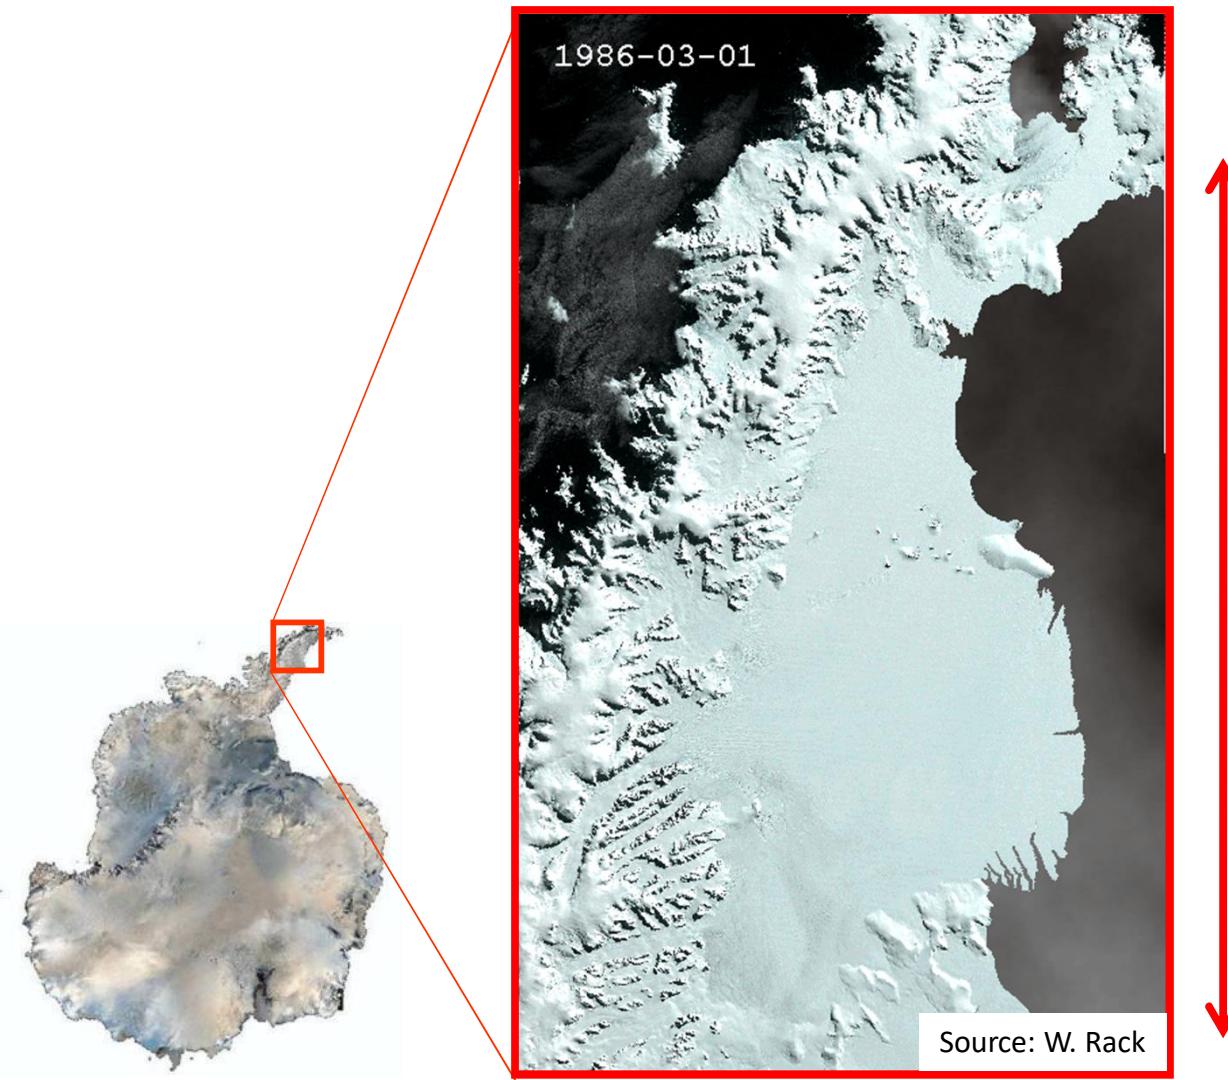

3 major types of changes to ice flow rate:

1. Faster ice flow in summer in Greenland
2. Rapidly disintegrating ice shelves
3. Rapid retreat, thinning and acceleration of outlet glaciers

Dramatic decade of ice sheet behavior

Requires >10,000  
years to form  
  
Disintegrate in  
weeks

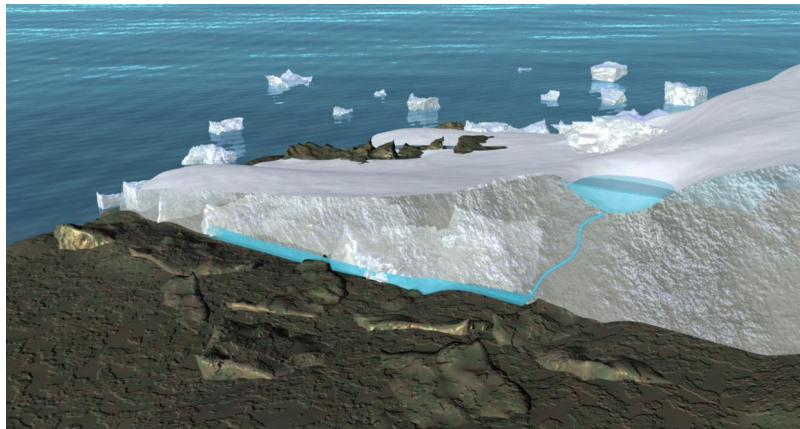

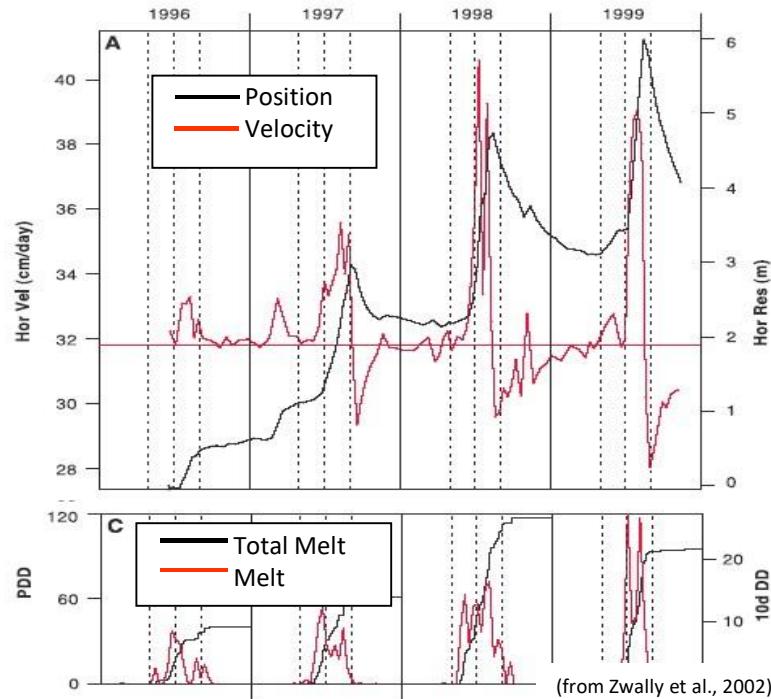

150 miles: Portland,  
to Seattle

# Water as a Lubricant

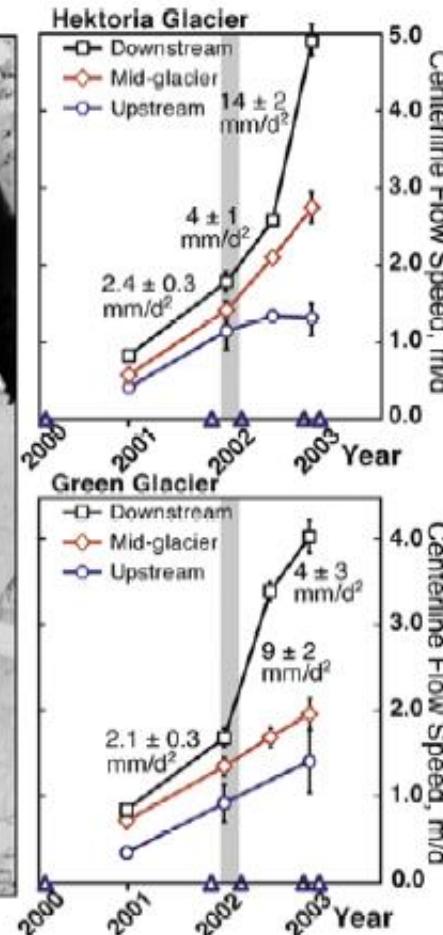

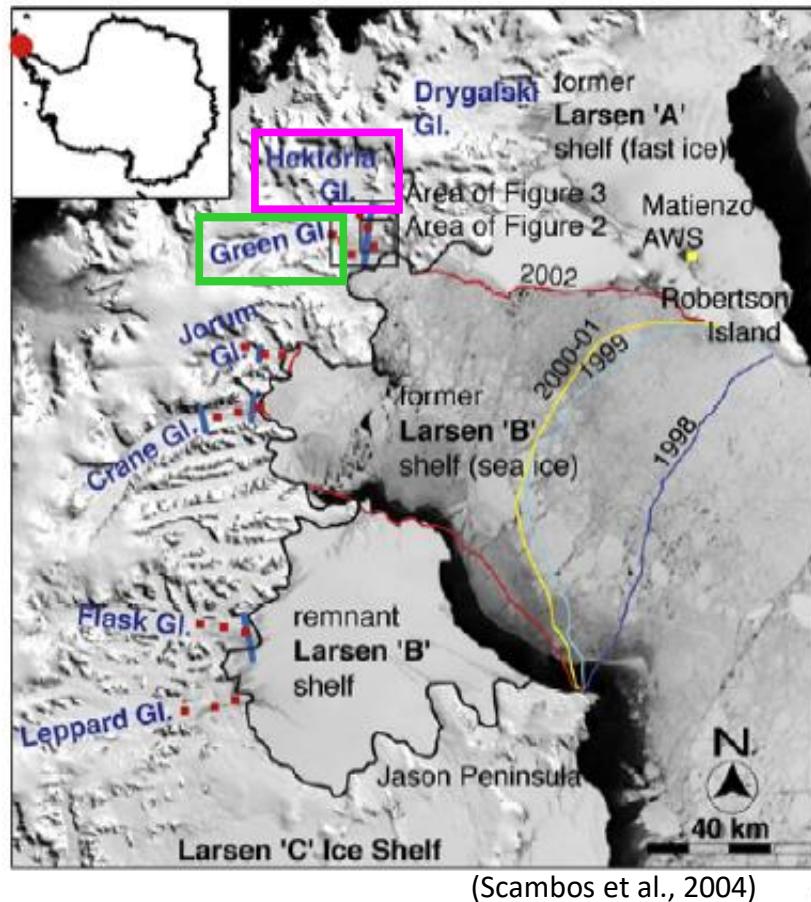

Glacier flow increases 10-15%  
Slower ice increases up to 70%

(from Joughin et al., 2008)

# Consequence of Ice Shelf Loss

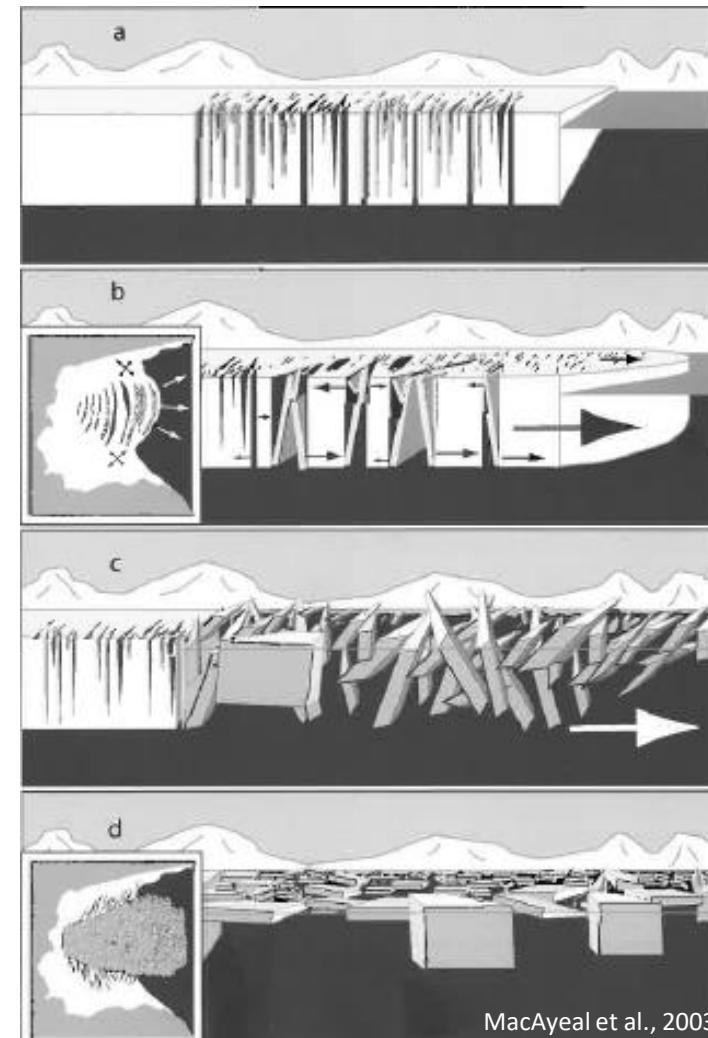

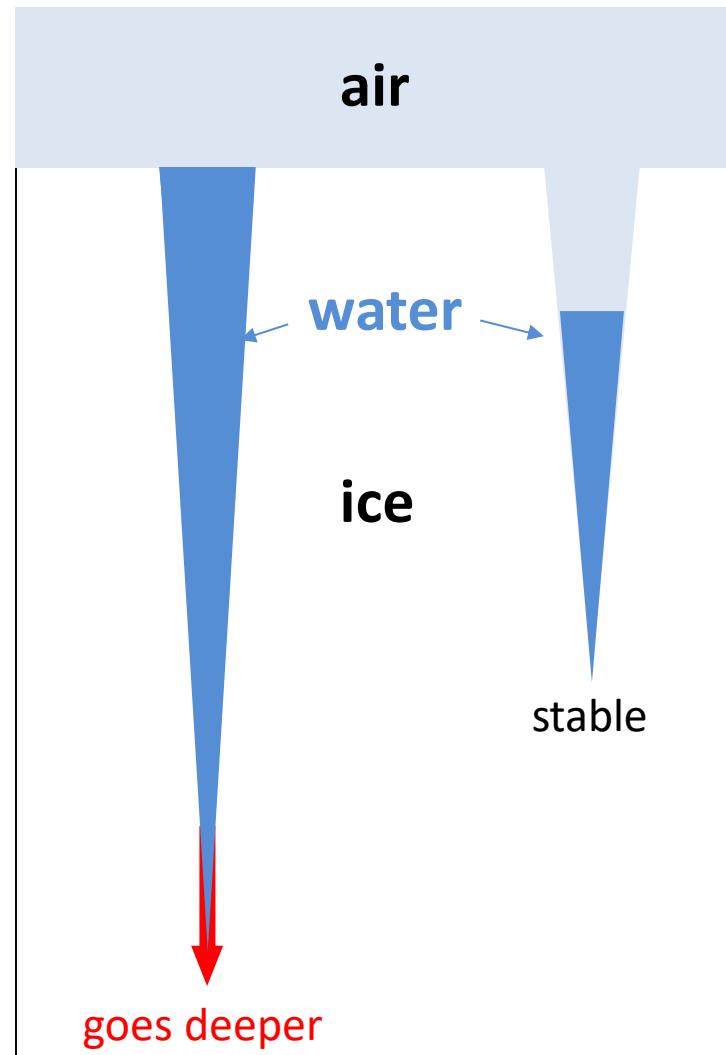

up to 510%  
faster in  
2 years

up to 400%  
faster in  
2 years

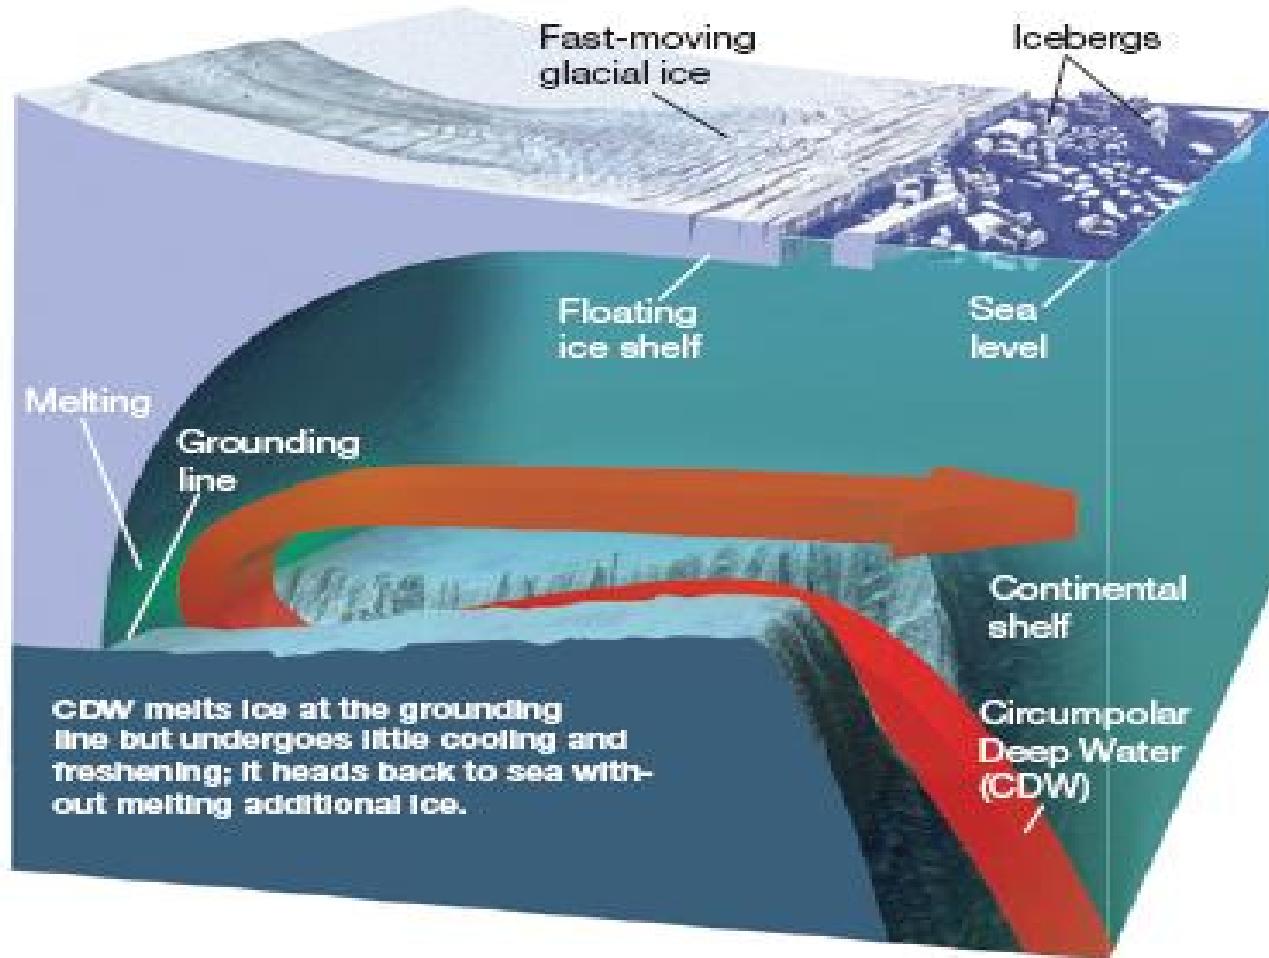

Formerly buttressed glaciers accelerate

## Water as a Wedge

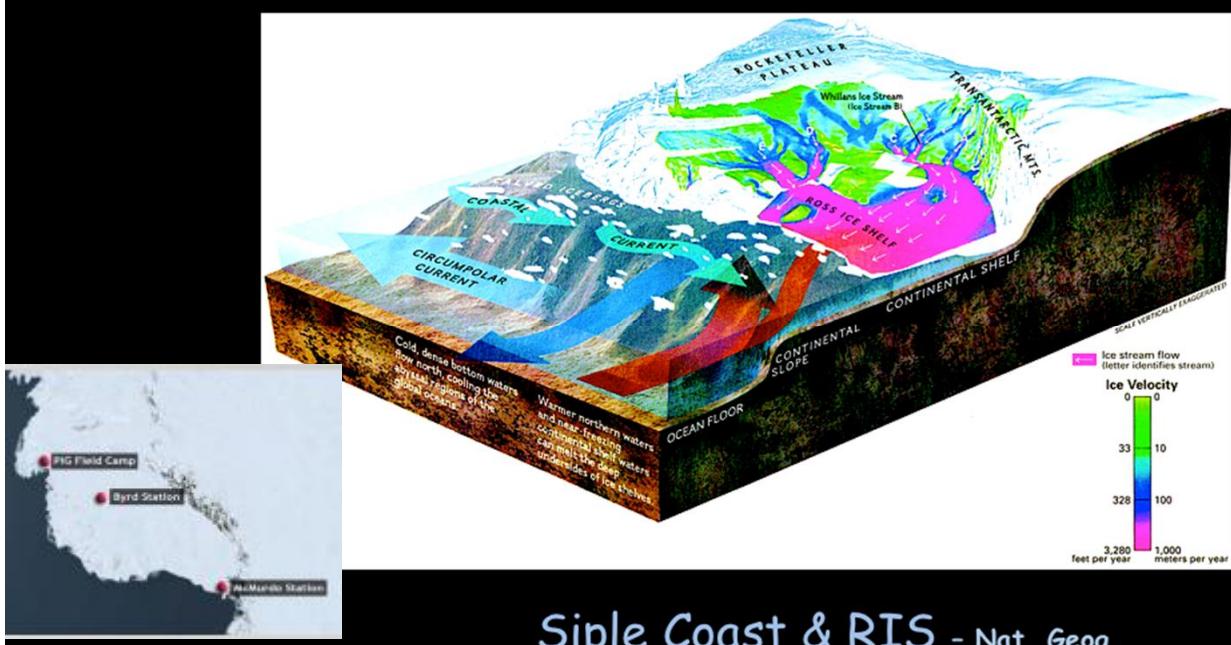

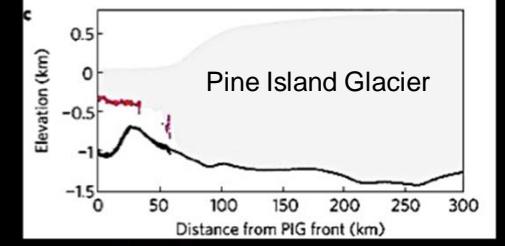

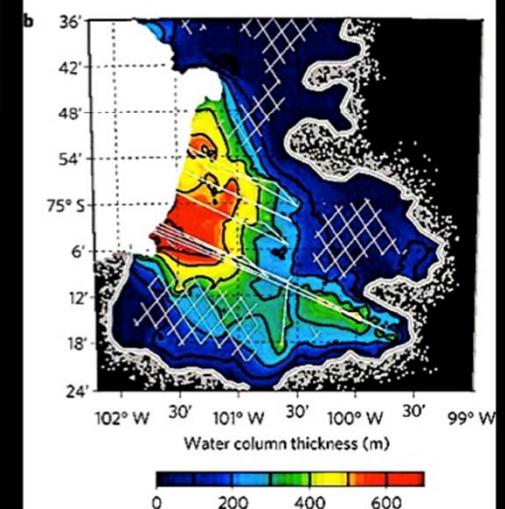

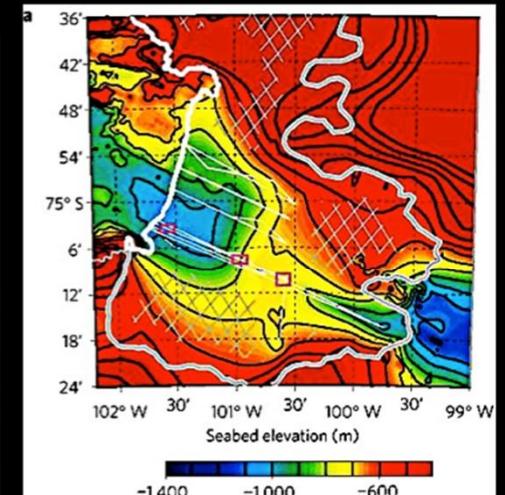

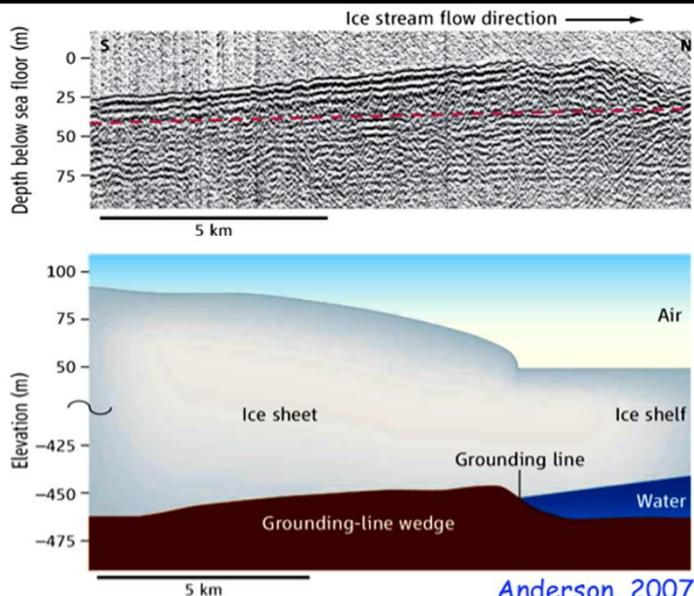

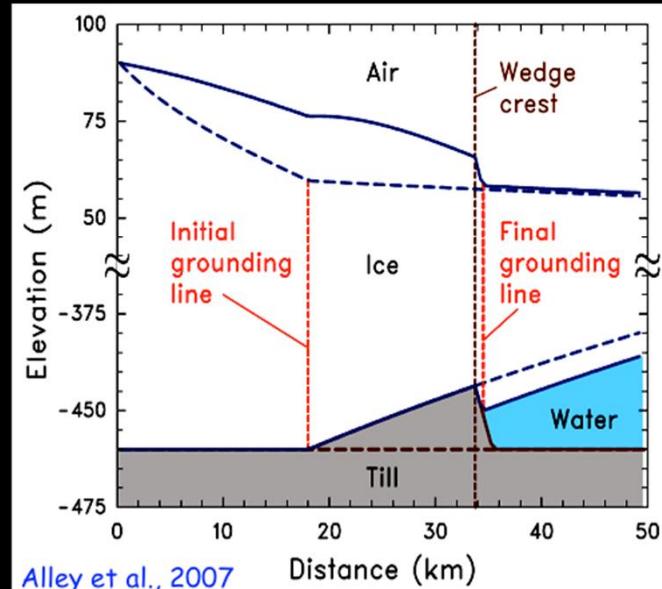

# Water as a Heater
