publications on nanoparticles

## A brief historical background

- gold nanoparticles are known since ancient time, 5<sup>o</sup> - 4<sup>o</sup> millenium B.C. (China, Egypt). We believe that ancient Egyptian known how to prepare "soluble" gold and they were used these solutions as "elisir".
- colloidal gold sols are used to obtain red glass
- around 1600 Paracelso (1493-1541) described the preparation of "aurum potable, oleum auri: quinta essentia auri" by reduction of acid tetrachloroauric using an alcoholic extract of plants.  
At that time medical doctors believed that "drinkable gold" exert curative properties for several diseases.

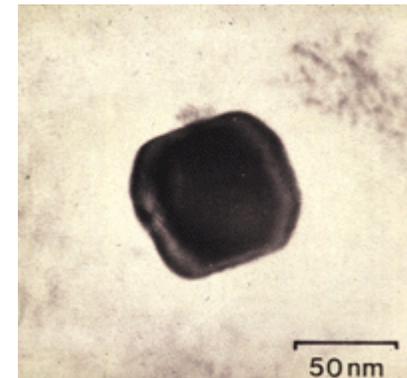

## A brief historical background

---

The roman industry of IV century A.D., developed a sophisticated use of metal NPs, they were able to produce colored glass with particular optical properties. For example the addition of Ag and Au compounds, enable to produce glass which appear to be green under reflected light and red under trasmitted light. The famous "Licurgus cup" has been realized with this technique.

Optical Properties

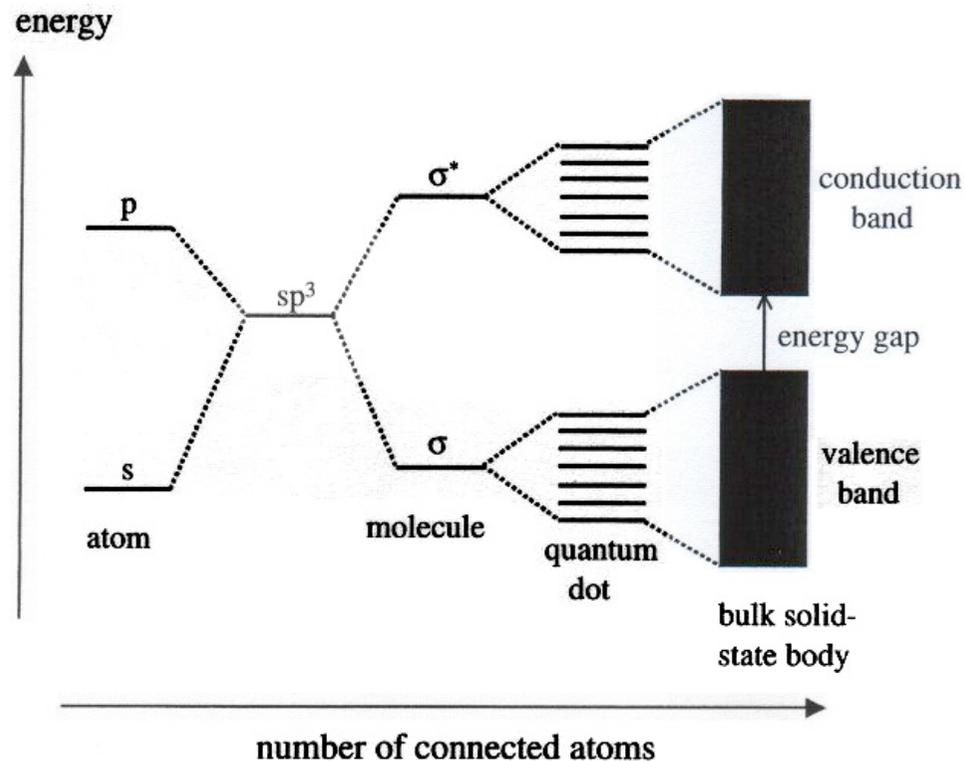

Electronic Properties

**Nanoscale Materials Have Different Properties when compared to their bulk counterparts!**

# Nanoscale Materials

**Fig. 2-1** Electronic energy levels depending on the number of bound atoms. By binding more and more atoms together, the discrete energy levels of the atomic orbitals merge into energy bands (here shown for a semiconducting

material) [16]. Therefore semiconducting nanocrystals (quantum dots) can be regarded as a hybrid between small molecules and bulk material.

# **Synthesis of metal nanoparticles**

---

## ***PVD (physical vapor deposition)***

### ***formation of clusters in the gas phase - Au metal as starting material***

for example, the nanoparticles are formed from bulk metal by irradiating it with a laser beam.

At low laser flux, the material is heated by the absorbed laser energy and evaporates or sublimates and deposited over a solid support, under UHV condition.

es. cathodic arc deposition, sputter deposition, electron beam physical vapor deposition, laser ablation

## ***CVD (chemical vapor deposition)***

### ***organometallic compounds as starting material***

In a typical CVD process, the wafer (substrate) is exposed to one or more volatile precursors, which react and/or decompose on the substrate surface to produce the desired deposit.

Frequently, volatile by-products are also produced, which are removed by gas flow through the reaction chamber.

***problem: control of the NP size***

# Synthesis of metal nanoparticles

- control of size, shape and composition with synthetic methodologies that allows to produce significative quantities of NPs.
- **molecular approach to colloidal metals**: use of molecular precursors
- many of the known methods are applicabile to different metallic elements of the periodic table, for exemple the reduction with hydrides.
- colloidal NPs are unstable and aggragate if not stibilized

# Synthesis of metal nanoparticles

---

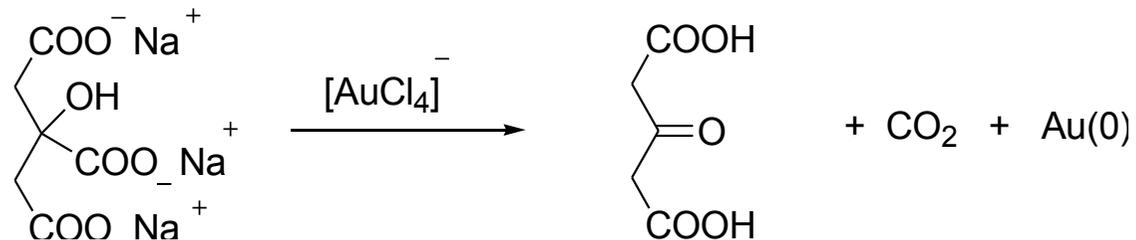

Two methods against aggregation:

• **electrostatic stabilization**

• **steric stabilization**

• 12-64 nm J. Turkevitch, P. C. Stevenson, J. Hillier, *Disc. Farady Soc.* **1951**, 11, 55.

Reduction with **sodium citrate** developed by Frens in 1973:  
this is the most used method for the preparation of gold colloids.

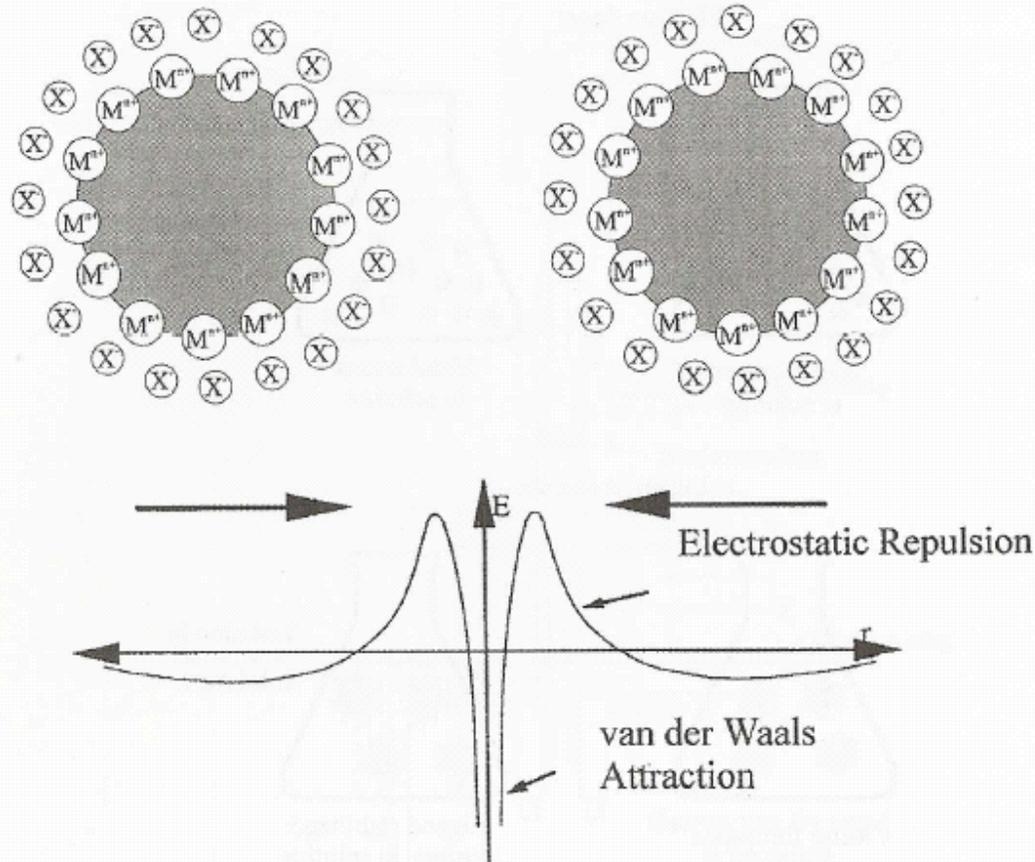

it is easy

- it requires only water
- it requires skills
- has reproducibility issues

NPs size may increase using more diluted solutions.

# Synthesis of metal nanoparticles

## Electrostatic stabilization: the electrical double layer

**FIGURE 2.24** Electrostatic stabilization of metal colloids. Van der Waals attraction and electrostatic repulsion compete with each other.<sup>27</sup>

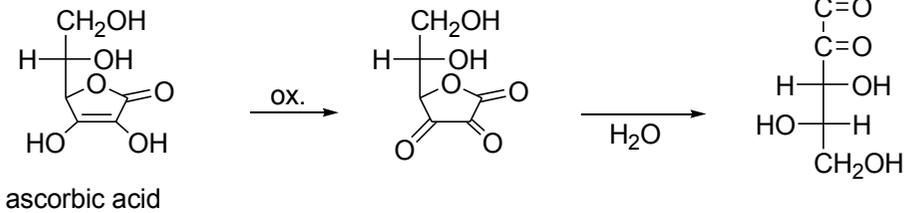

the energetic maximum can be easily overcome increasing for example the ionic strength or by increasing the thermal movement of the NPs.

# Synthesis of metal nanoparticles

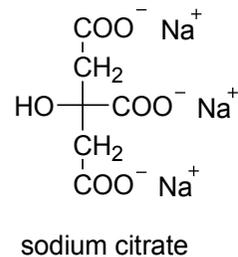

## reduction of $\text{HAuCl}_4$ with different reducing agents

● 3-4 nm sodium borohydride ( $\text{NaBH}_4$ )

● 12 nm

● 12-64 nm

# Synthesis of metal nanoparticles

---

- the strength of the reducing agent determine the NP size
- the reaction conditions are also very important in determining the average diameter
  - the size may be reduced by: increasing reductant  
decreasing volume  
increasing stirring  
increasing temperature

# Synthesis of metal nanoparticles

---

## Steric stabilization

polymers, surfactants, and legands may be used to form a protective monolayer

**polymers**: they should present specific groups that bound to the NPs surface

**Gold Number**: quantity of polymer that stabilize 1 g of a solution of 50 mg/L of colloidal gold against aggregation in the presence of NaCl 1%

**PVP** [poly(vinylpyrrolidone)] and **PVA**, poly(vinyl alcohol) o  
**CTAB** (cetyltrimethylammonium bromide)

These polymers have been used also to stabilize Pt and Ag NPs

# Synthesis of metal nanoparticles

---

## reduction of transition metals salts

- by using solvents that may easily be oxidized as alcohols that are oxidized to aldehydes or ketones
- Hirai and Toshima, “alcohol reduction process” and polymers for the stabilization

Other reducing agents:

Ascorbic acid, hydrogen, formaldehyde, hydrazine

# Characterization of NPs

---

Step 4. Column chromatography to remove  $\text{PPh}_3\text{O}$ ,  $\text{Ph}_3\text{PAuCl}$ ,  $[\text{CH}_3(\text{CH}_2)_{11}\text{S}]_2$

"undecagold" derivatives have been widely used as markers of biological compounds and for histochemical analysis

P. A. Bartlett, B. Bauer, S. J. Singer, *J. Am. Chem. Soc.* **1978**, *100*, 5085.

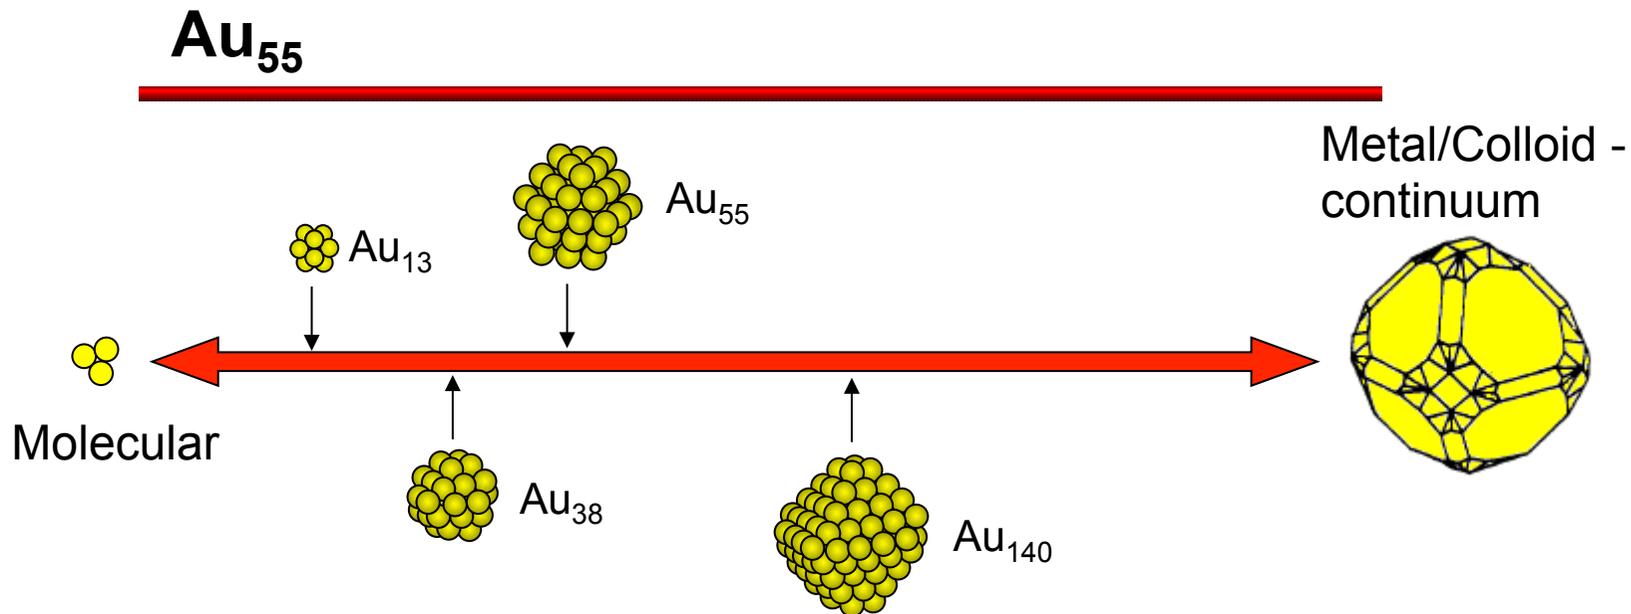

F. Cariati, L. Naldini, *Inorg. Chim. Acta*, **1971**, *5*, 172.

# UNDECAGOLD

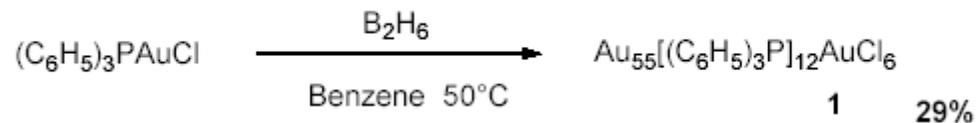

H. Yang, P. A. Frey, *Biochemistry*, **1984**, 23, 3849, 3857, 3863.

- conjugates of peptide, ATP, nucleic acids, lipids, phospholipids, carbohydrates, antibodies, etc. have been prepared.

$\text{Au}_{55}(\text{PPh}_3)_{12}\text{Cl}_6$  is the most studied full-shell cluster since it represents a transition between molecular and colloidal behaviour

the synthetic method enables one to obtain a monodispersed cluster and because of this it could be used in the formation of fcc 3D crystals .

## Synthesis of Thiol-derivatised Gold Nanoparticles in a Two-phase Liquid-Liquid System

Mathias Brust, Meryll Walker, Donald Bethell, David J. Schiffrin and Robin Whyman

Department of Chemistry, The University of Liverpool, PO Box 147, Liverpool, UK L69 3BX

Using two-phase (water-toluene) reduction of  $\text{AuCl}_4^-$  by sodium borohydride in the presence of an alkanethiol, solutions of 1–3 nm gold particles bearing a surface coating of thiol have been prepared and characterised; this novel material can be handled as a simple chemical compound.

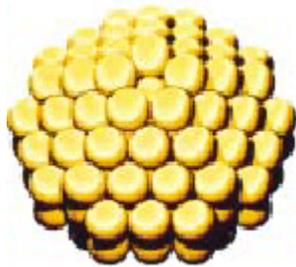

⇒ MPCs OF DIFFERENT SIZE MAY BE OBTAINED USING DIFFERENT REACTION CONDITIONS:

- RATIO  $\text{RSH}/\text{Au}$
- REDUCTION RATE
- TEMPERATURE

# 3D alkanethiolate monolayers

**Scheme 1.** A Schematic 2D Representation of the RS/Au Nanoparticle Packing Structure in the Solid State<sup>a</sup>

<sup>a</sup> In this description, *domains* or *bundles* of ordered alkanethiolate chains on a given Au particle will interdigitate into the chain domains of neighboring particles in order to compensate for the substantial decrease in the chain density which occurs toward the methyl chain end. Chains with large populations of *gauche* bonds may arise from (i) those which occupy interstitial regions in the particle lattice and cannot efficiently overlap with adjacent chains or from (ii) chains residing at domain boundaries.

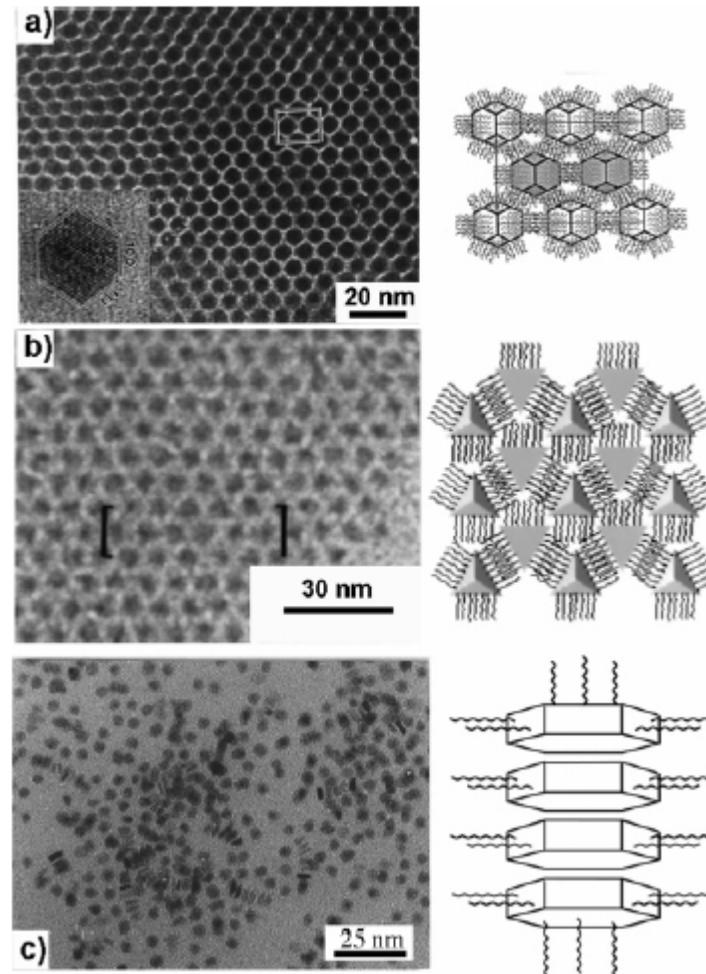

**Scheme 2.** The Types of Chain Dynamic Processes Suggested by the <sup>2</sup>H NMR Line Shapes of the Deuterated C<sub>18</sub>S/Au Nanoparticles<sup>a</sup>

<sup>a</sup> These processes involve *trans-gauche* bond isomerization and pseudorotational motion of individual chain segments about the long axis of the alkanethiolate molecule.

# 3D alkanethiolate monolayers

ITCAE pentapeptide <sup>h</sup>	no	1.4 ± 0.4	yes	days	Hutchison	not tested

<sup>a</sup> Brust synthesis was in 1:1 water:methanol with a 3:1 thiolate:gold ratio. Typical concentrations were 10 mM gold and 30 mM thiolate. A 5-fold molar excess of NaBH<sub>4</sub> in a volume of water ~10% of the reaction volume was added to complete the cluster formation. Reactions denoted Hutchison were performed as described (ref 5). <sup>b</sup> A 1:1 ratio of thiolate:Au(III) and a 9-fold BH<sub>4</sub><sup>-</sup> excess. <sup>c</sup> Cystine was used as the starting material to create cysteine MPCs. <sup>d</sup> Highest organothiolate:Au(III) ratio used was 5:2, with equimolar NaBH<sub>4</sub> to HAuCl<sub>4</sub>, likely resulting in incomplete reduction. <sup>e</sup> A 1.8:1 thiolate:Au(III) ratio was used. <sup>f</sup> These compounds failed to form soluble products in 1:1 water:methanol, but did so under similar conditions in 6:1 methanol:acetic acid. <sup>g</sup> This compound formed product that remained in suspension following low-speed centrifugation, indicating cluster formation, but failed to redissolve after methanol precipitation; this product was not repeatably precipitable in methanol, but could be purified from starting materials by gel filtration and, otherwise, behaved as a stable water-soluble MPC. <sup>h</sup> The pentapeptide had the sequence Ile-Thr-Cys-Ala-Glu. <sup>i</sup> LD-PAGE was a standard 12% SDS-PAGE gel. <sup>j</sup> Particles form aggregates within which individual particle diameters cannot be measured. <sup>k</sup> See Supporting Information for images, histograms, and further analysis.

**Table 1** Contrasts of the phases in the hybrid particles (in units  $10^{-6} \text{ \AA}^{-2}$ ) (a) and discrepancy of the fits (b)

(a) Contrasts	C6 : d-C12	d-C6 : C12
Phase 1 : gold	1.4	1.4
Phase 2 : C12	2.5	-3.4
Phase 3 : C6	-3.4	1.9
(b) Discrepancy values <sup>a</sup>	C6 : d-C12	d-C6 : C12
Striped particle	1.2	1.1
Janus particle	15.2	7.7
Randomly mixed particles	1.8	4.2

<sup>a</sup> Chi squared.

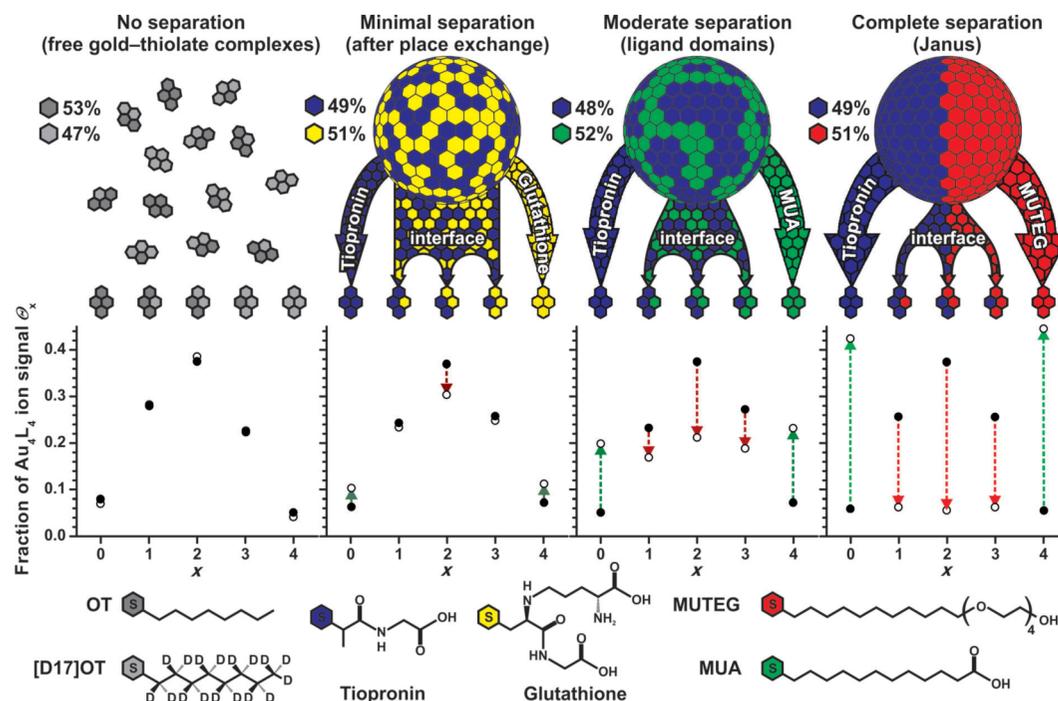

**Fig. 5** Four different projections of a typical multiphase 3D low-resolution model of the C6 : C12 particles obtained from the fitting of the SANS data. Yellow beads indicate the gold nanoparticle core regions, the magenta beads represent the C6 moiety, and the cyan beads the C12 moiety. The beads in the model act as low-resolution place holders to depict the space occupied by the gold, C6 and C12 moieties. The image (d) on the right has the cyan beads in a lower transparency mode to highlight the C12 moieties. The C6 regions form elongated domains within the bulk of the C12 phase in excellent agreement with the model of striped nanoparticles. Scale bar, 5 nm. The arrows indicate elongated C6 domains that roughly align along a preferential direction. These features would provide aligned domain boundaries in the STM images (the arrows are spaced by about 1 nm).

# Characterization of Ligand Shell for Mixed-Ligand Coated Gold Nanoparticles

Quy Ong,<sup>†</sup> Zhi Luo,<sup>†</sup> and Francesco Stellacci\*<sup>‡</sup>

DOI: 10.1021/acs.accounts.7b00165  
Acc. Chem. Res. 2017, 50, 1911–1919

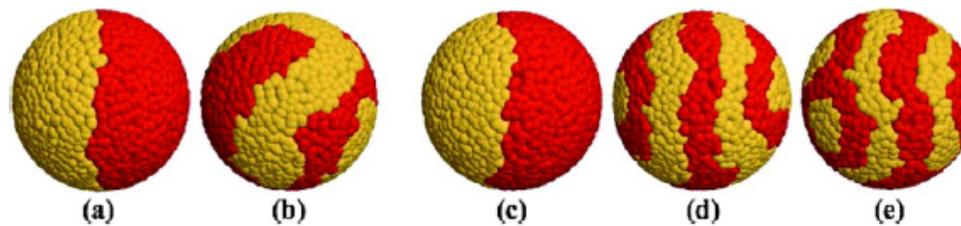

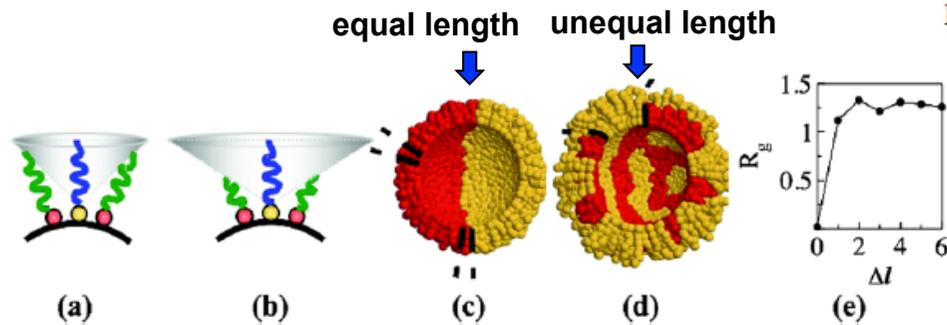

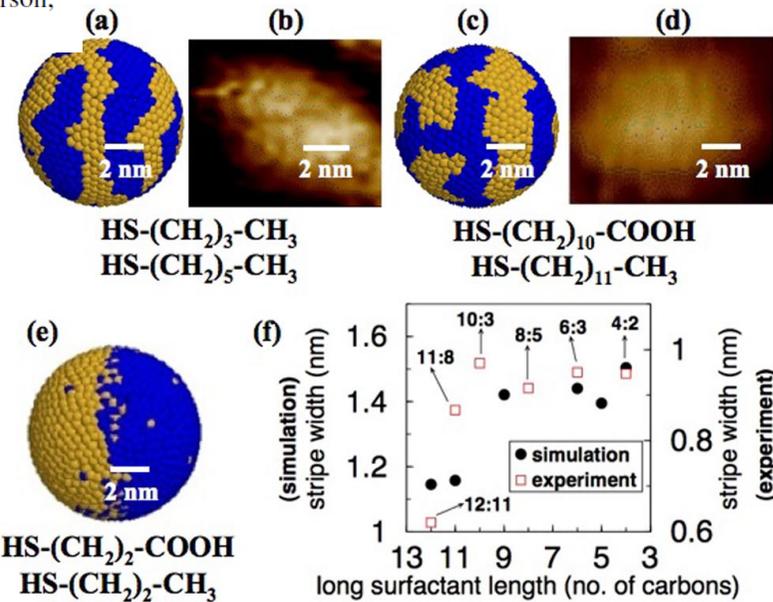

**Figure 5.** MALDI-MS investigation of molecular phase separation in mixed ligand coated NPs. Among the fragments of Au-thiol complexes caused by the MALDI process, only the  $Au_4L_4$  ion species are analyzed since they are the most abundant fragments. For a binary ligand coated gold NP, 5 combinations of  $Au_4L_4$  will be found and they are labeled from 0 to 4 in the  $x$ -axis of the plots. In other words, if the ligand shell contains a binary mixture of thiols A and B, the 5 species of the  $Au_4L_4$  complexes analyzed are  $Au_4A_{4-x}B_x$  ( $x = 0, 1, 2, 3, 4$ ). Their corresponding abundances obtained experimentally from 4 different types of mixed ligand coated gold NPs are illustrated by open circles. The binomial distribution, which corresponds to random morphology, is presented by filled black dots. The deviations from the binomial distribution, represented by an arrow for each species, indicate the presence of molecular phase separation in the ligand shell that ranges from completely mixed, to patchy domains, and to the Janus structure. The ligand shell compositions of the 4 investigated particles are octanethiol (OT)/deuterated OT, tiopronin/glutathione, 11-mercaptoundecanoic (MUA)/glutathione, tiopronin/mercaptoundecyltetraethylene glycol (MUTEG), respectively. **Figure 5 Schematic drawing of a generic protein (top) and a rippled nanoparticle (bottom).** The pink and blue contour line on top of the nanoparticle shows the hydrophobic and the hydrophilic regions of the particle, respectively. The same colour scheme is used to show the outside shell of the chosen protein. It is evident (as the drawing is approximately to scale) how, despite the enormous conformational freedom that the proteins have, there will always be regions of attraction and regions of repulsion when interacting with nanostructured nanoparticles.

# protein nonspecific absorption

Proteins can assume a few possible conformations as determined by molecular structure

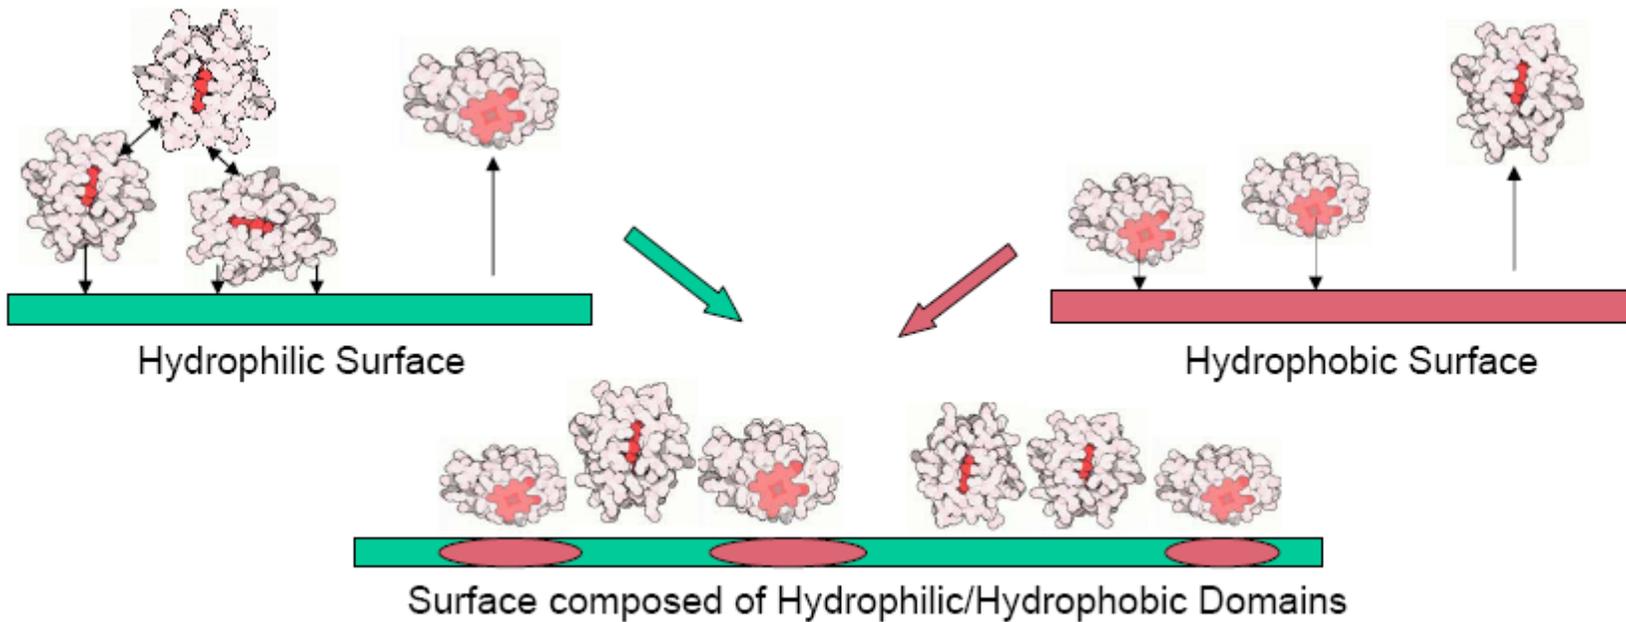

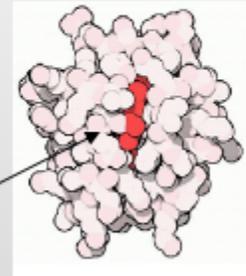

1) Maximizes exposure of hydrophobic region

2) Minimizes exposure of hydrophobic region

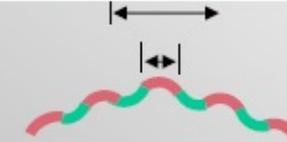

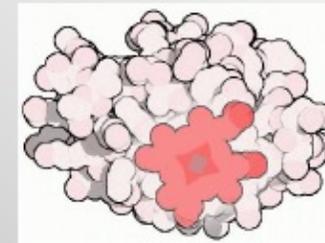

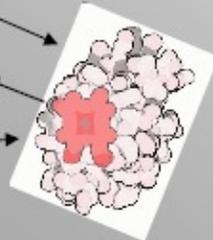

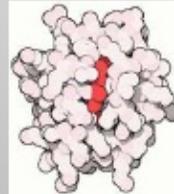

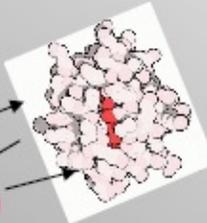

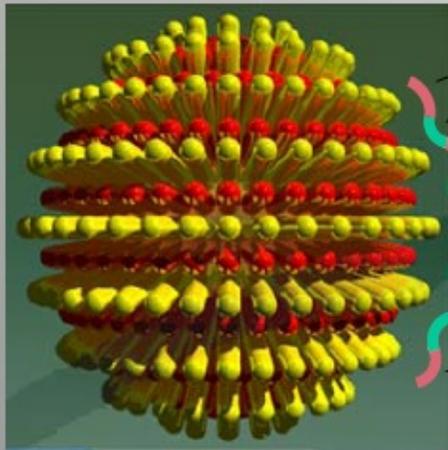

Hydrophilic region

Hydrophobic region

# The Nano Lotus Leaf Effect

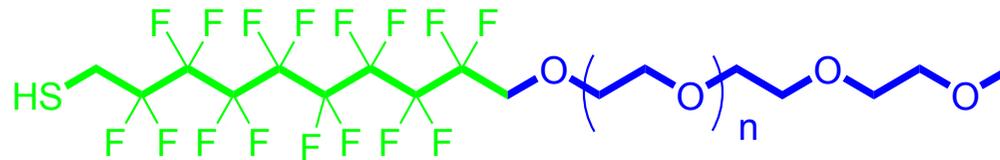

Size of hydrophobic/hydrophilic regions of protein are greater than size scale of ligand domains on the nanoparticles.

Proteins are **conformationally frustrated** and cannot adsorb to nanoparticle surface.

# gold nanorods

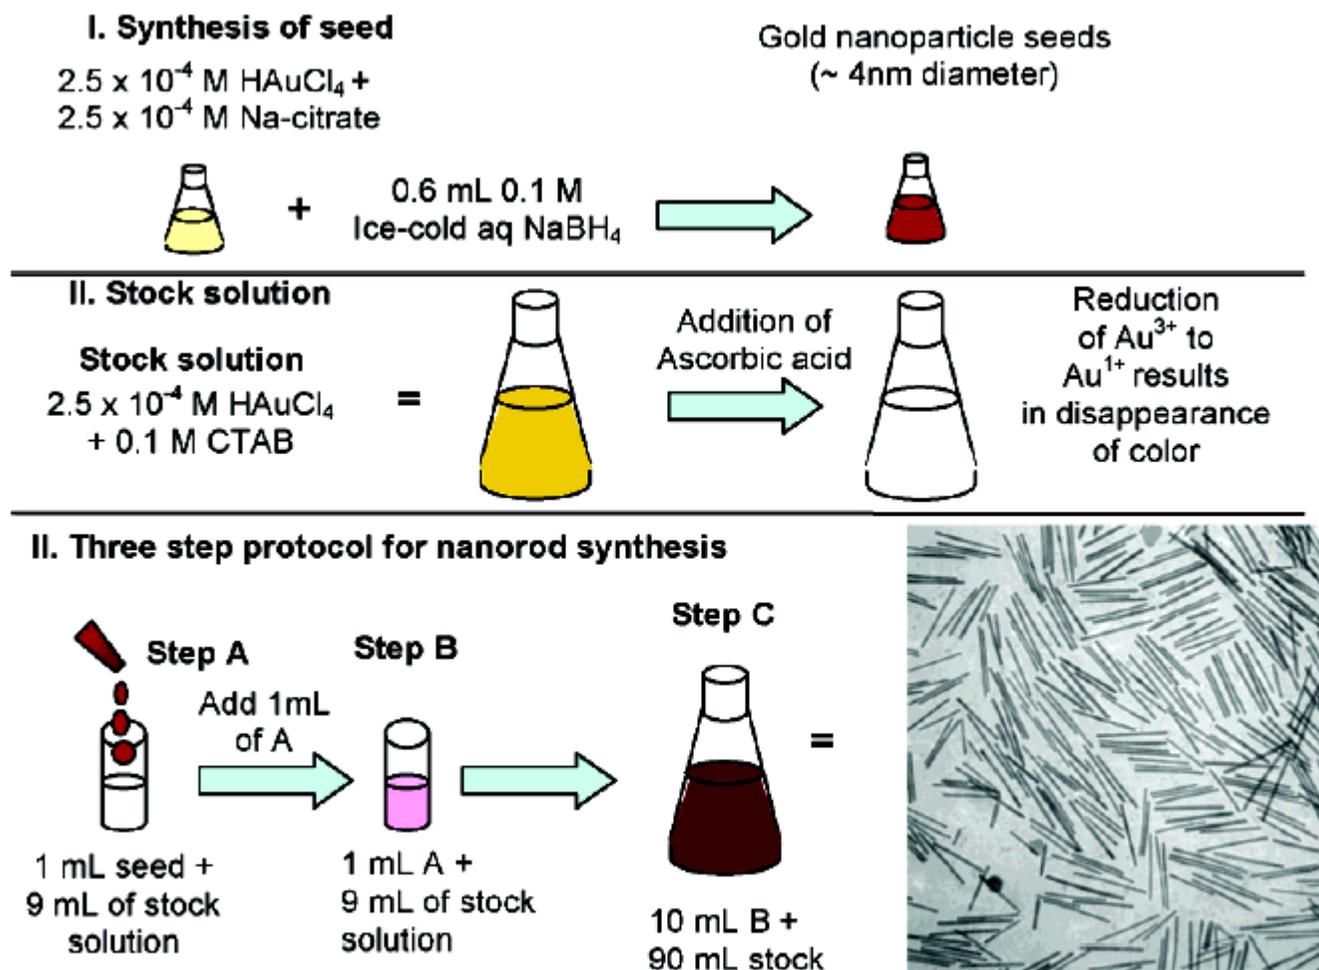

## Seed-mediated Growth in Solution

1. Chemical reduction of a metal salt with strong reducing agent ( $\text{NaBH}_4$ ),
2. Use of a capping agent to prevent particle growth (citrate),
3. Addition of the seeds to a solution that contains more metal salt, a weak reducing agent (AA) and a rodlike micellar template (cetyltrimethylammonium bromide, CTAB).

Aspect ratio is controlled by the ratio of metal seed to metal salt.

# gold nanorods

**Figure 2.** Seed-mediated growth approach to making gold and silver nanorods of controlled aspect ratio. The specific conditions shown here, for 20 mL volume of seed solution, lead to high-aspect ratio gold nanorods. (bottom right) Transmission electron micrograph of gold nanorods that are an average of 500 nm long.

# gold nanorods

---

## Influence of the reaction parameters

- ✓ Effect of the Seed Concentration

An **increase** in the  $[\text{Au}]_{\text{seed}}$  **decreased** the **rod length** for a given concentration of  $\text{Au}^{3+}$ .

- ✓ Effect of AA concentration

The **rod length decreases** with an **increase in [AA]** keeping all other conditions the same.

- ✓ Effect of  $\text{AgNO}_3$

When **silver nitrate** is **not used** nanorods are obtained in **low yield** and quite **long**.

- ✓ Effect of  $[\text{Au}^{3+}]$

The **less** quantity of  **$\text{Au}^{3+}$  ions** per seed particle available the **short** are the nanorods.

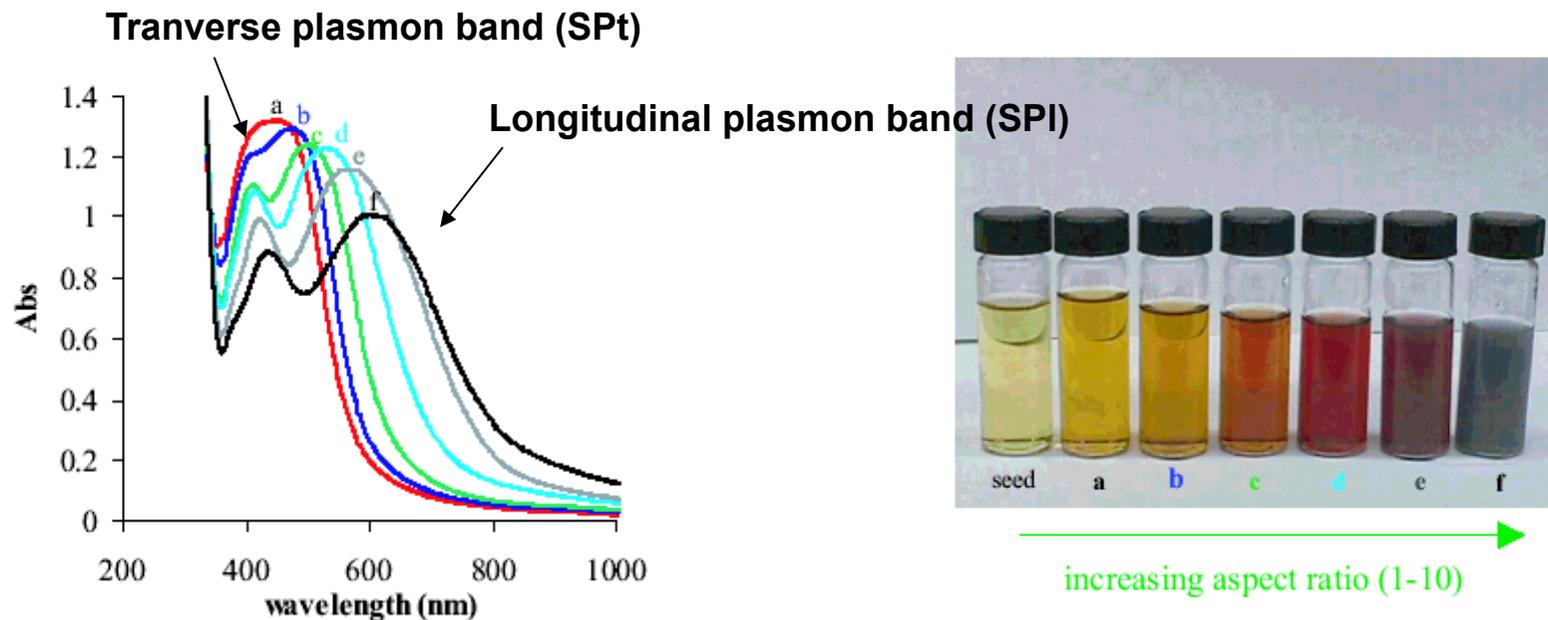

- ✓ Effect of [CTAB]

**Lower CTAB** concentrations can lead to **non-rod-shaped** particles.

# gold nanorods

## Variation in the absorption of visible light

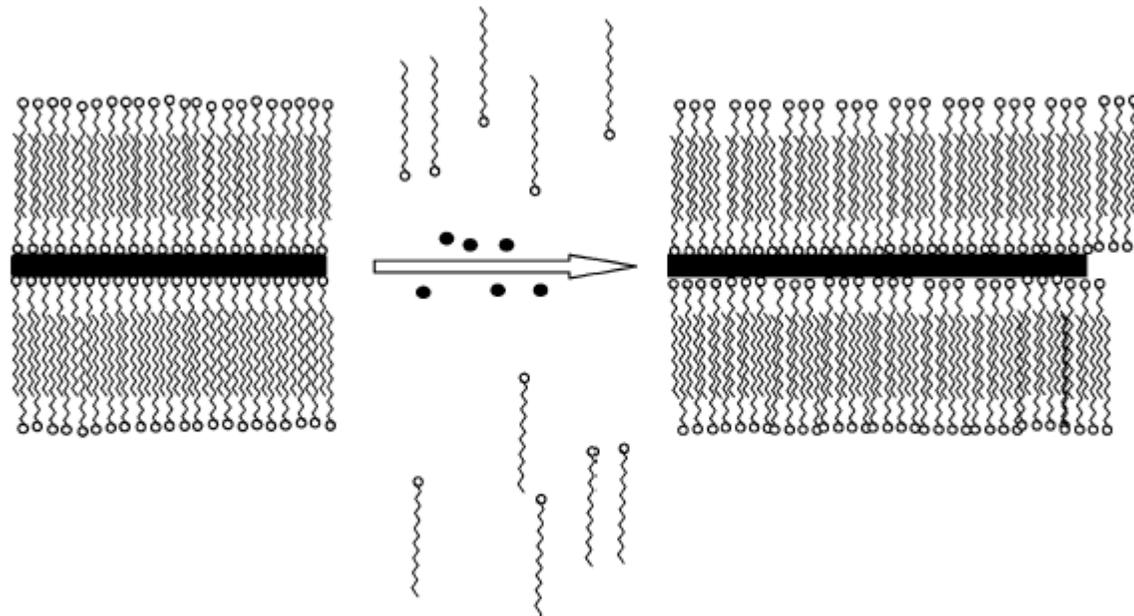

Short aspect ratio Au nanorods are especially interesting because of their optical properties: they exhibit transverse and longitudinal plasmon bands.

Aspect ratio: the length of the major axis divided by the width of the minor axis.  
The larger the aspect ratio, the more red-shifted the longitudinal plasmon band.

# gold nanorods

---

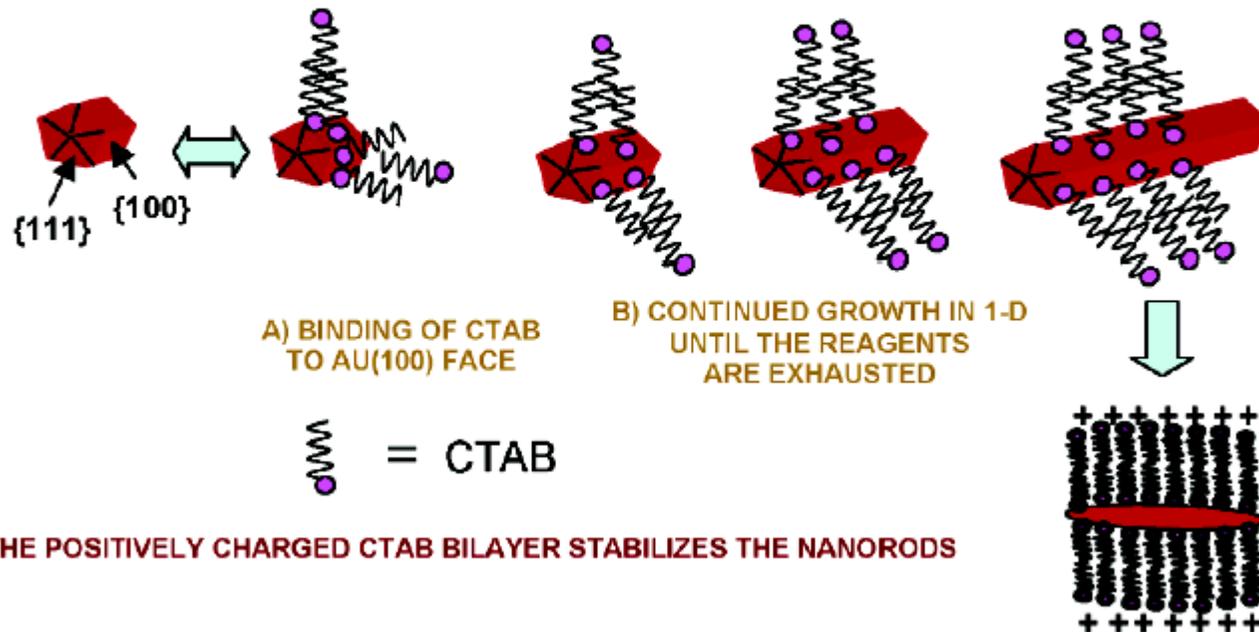

**Figure 7.** Cartoon illustrating “zipping”: the formation of the bilayer of CnTAB (squiggles) on the nanorod (black rectangle) surface may assist nanorod formation as more gold ion (black dots) is introduced. Reproduced from ref 104 with permission.

# gold nanorods

## STEP 1: SYMMETRY BREAKING IN FCC METALS

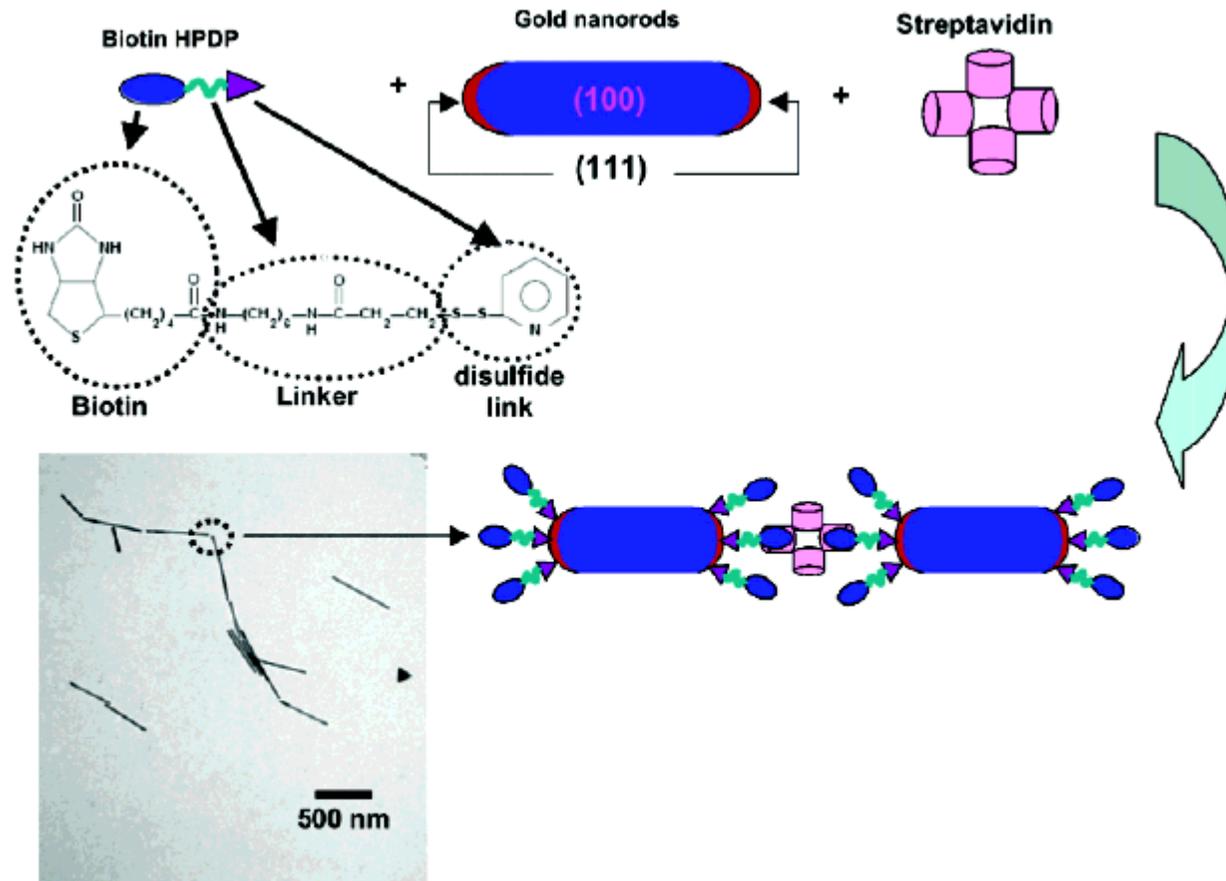

## STEP 2: PREFERENTIAL SURFACTANT BINDING TO SPECIFIC CRYSTAL FACES

**Figure 8.** Proposed mechanism of surfactant-directed metal nanorod growth. The single crystalline seed particles have facets that are differentially blocked by surfactant (or an initial halide layer that then electrostatically attracts the cationic surfactant). Subsequent addition of metal ions and weak reducing agent lead to metallic growth at the exposed particle faces. In this example, the pentatetrahedral twin formation leads to Au {111} faces that are on the ends of the nanorods, leaving less stable faces of gold as the side faces, which are bound by the surfactant bilayer.

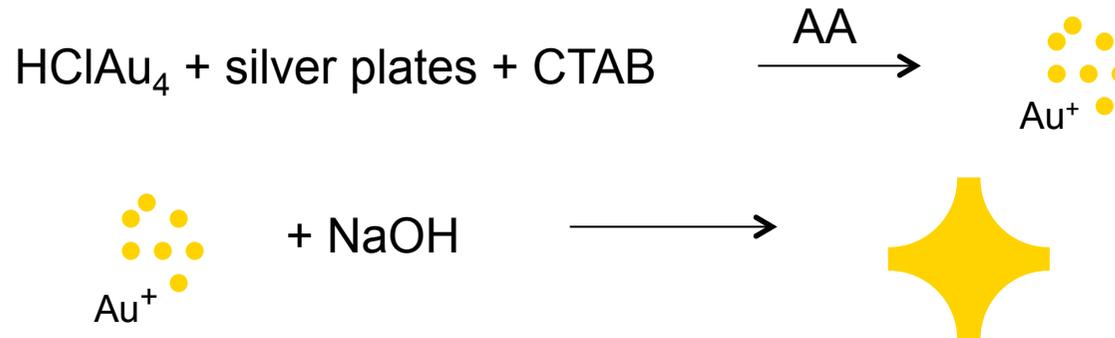

# gold nanorods - functionalization

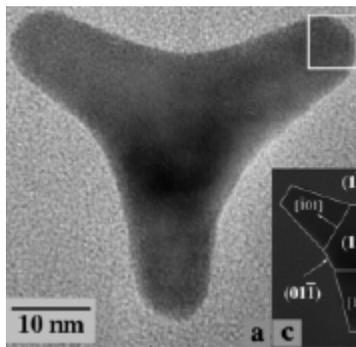

**Figure 9.** Cartoon of biotin-streptavidin assembly of gold nanorods; a biotin disulfide is added to biotinylate the rods, and subsequent addition of streptavidin causes noncovalent assembly. Inset: transmission electron micrograph of gold nanorod-streptavidin assemblies. The original data are from ref 86.

# Nanoparticle-based Sensors

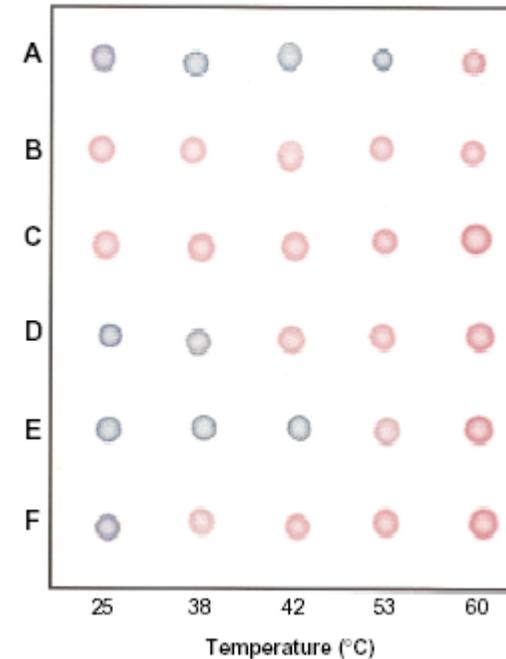

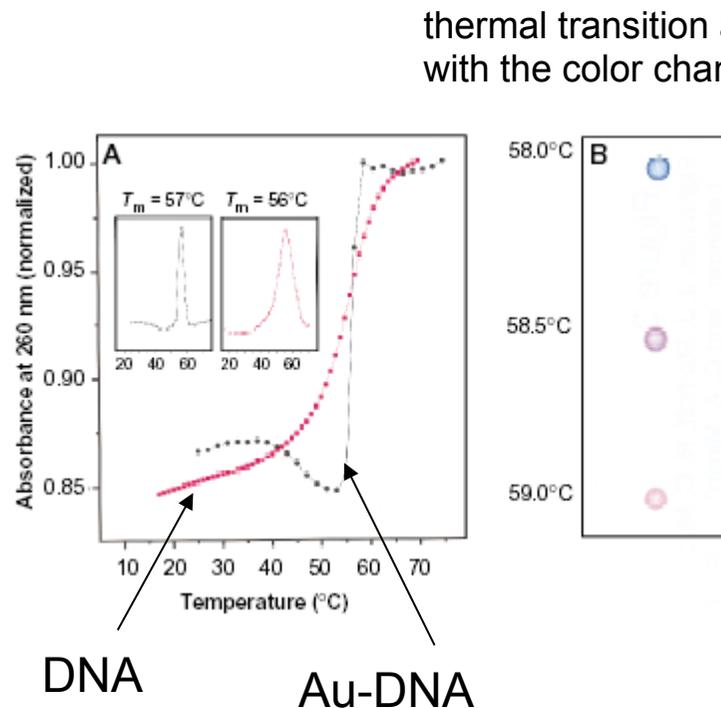

**Figure 7.** Forming DNA-mediated dimers of Au nanoparticles requires each nanoparticle to be functionalized with one oligonucleotide, with both oligonucleotides being complementary to each other. a) When phosphine- (or citric acid) stabilized Au nanoparticles and thiol-modified oligonucleotides react, DNA binds with its thiol group to the Au surface. However, even for 1:1 mixtures of DNA and Au, Au nanoparticles with more or less than one bound oligonucleotide will result; b) Au nanoparticles with a different number of DNA molecules bound per particle can be sorted by gel electrophoresis (image adapted from ref. [87]). Individual bands of nanoparticles with a discrete number of DNA molecules per particle can be observed and extracted from the gel; c) Au nanoparticles with one DNA molecule can be mixed with another solution of Au nanoparticles modified with a complementary DNA sequence. The single-stranded DNA molecules hybridize to a double strand, thus connecting the Au nanoparticles. The resulting dimers can be observed by TEM imaging (the Au-nanoparticle dimers shown comprise two 10-nm-diameter Au nanocrystals; the DNA molecules cannot be seen by TEM). Image courtesy of D. Zanchet et al.<sup>[7]</sup>

# Hybrid Nanoparticle–Liposome Detection of Phospholipase Activity

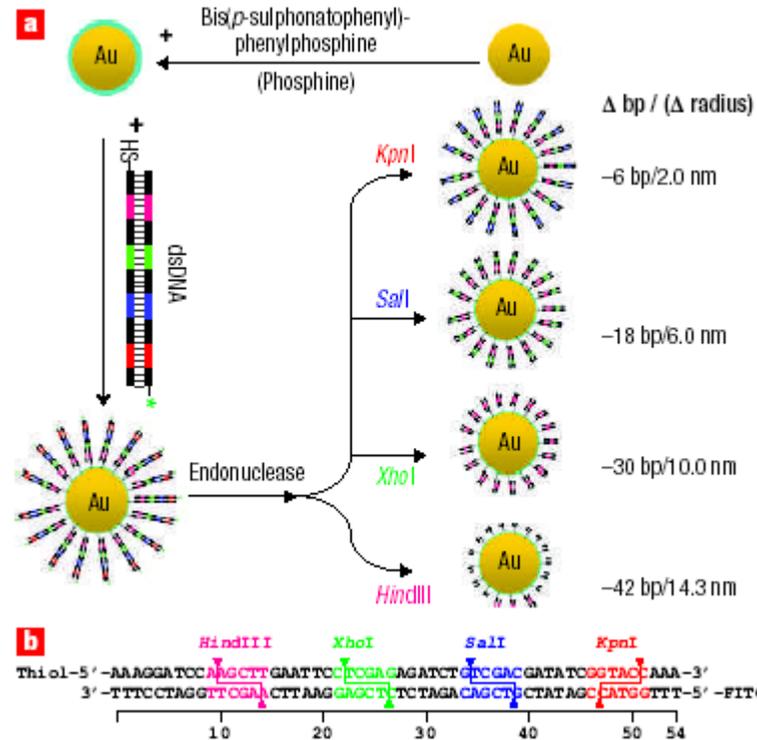

Daniel Aili<sup>†</sup>, Morgan Mager<sup>†</sup>, David Roche and Molly M. Stevens  
*Nano Letters* 2010

A flexible nanoparticle-based **phospholipase** (PL) assay is demonstrated in which the enzymatic substrate is decoupled from the nanoparticle surface. Liposomes are loaded with a polypeptide that is designed to heteroassociate with a second polypeptide immobilized on gold nanoparticles. Release of this polypeptide from the liposomes, triggered by PL, induces a folding-dependent nanoparticle bridging aggregation. The colorimetric response from this aggregation enables straightforward and continuous detection of PL in the picomolar range. The speed, specificity, and flexibility of this assay make it appropriate for a range of applications, from point of care diagnostics to high-throughput pharmaceutical screening.

# A nanoplasmonic molecular ruler for measuring nuclease activity and DNA footprinting

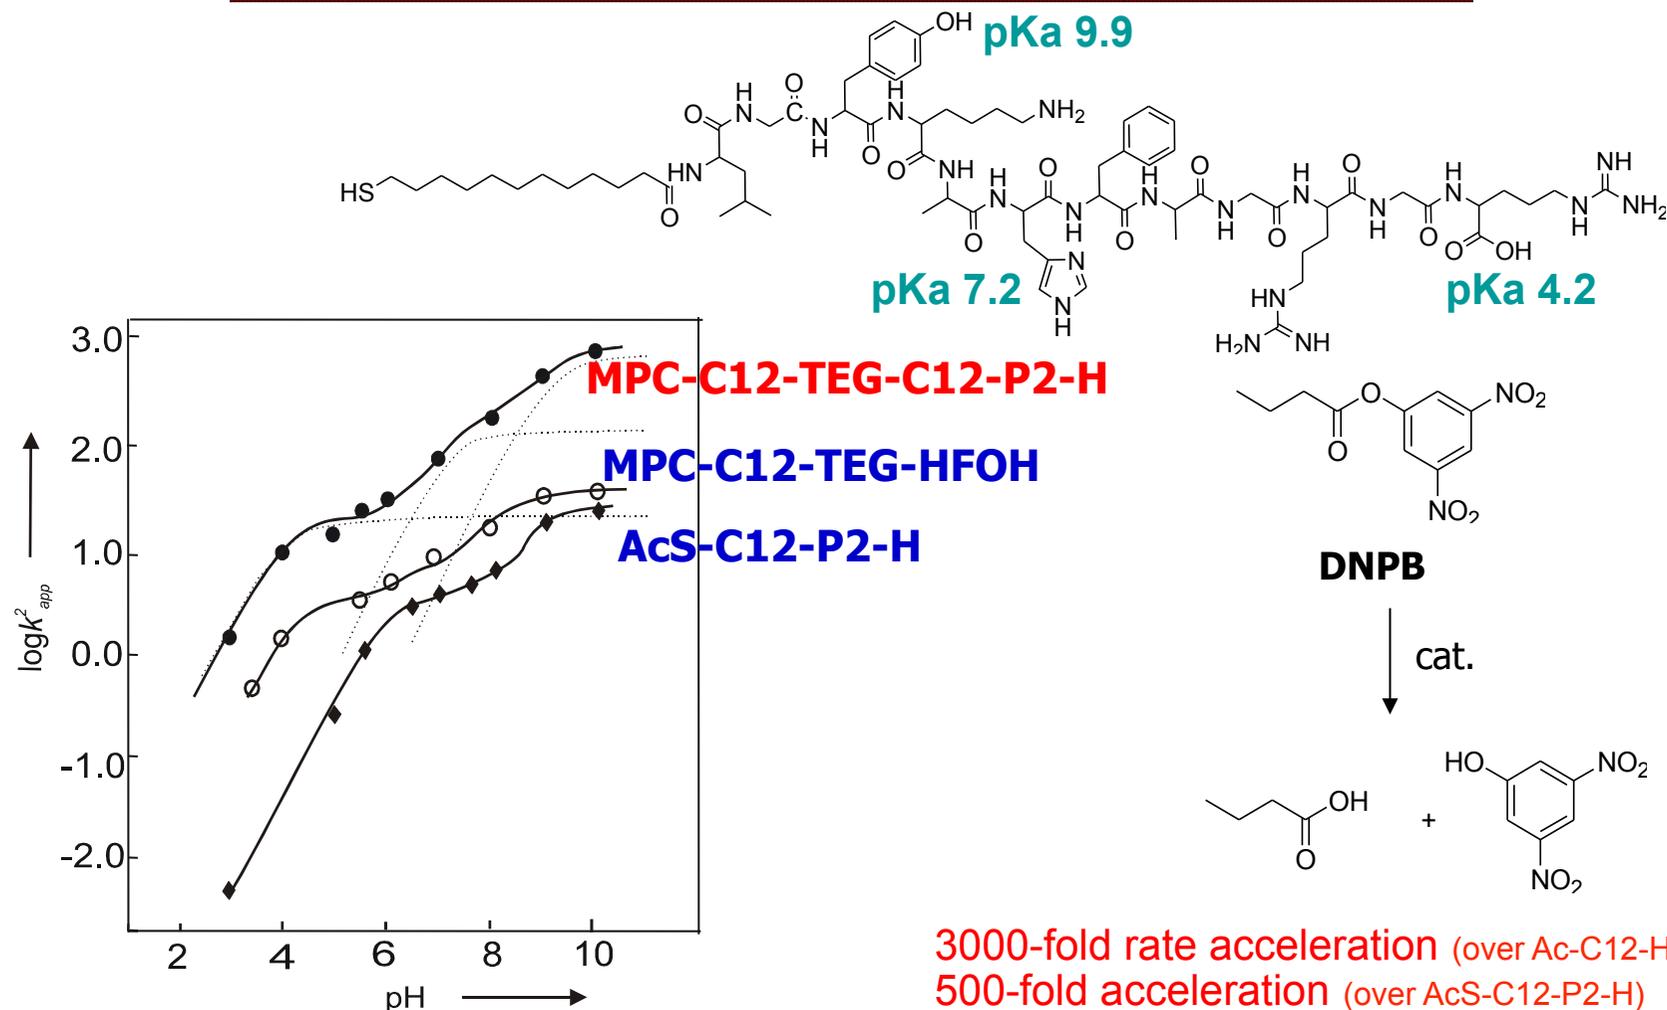

**Figure 1.** Design of the Au–DNA nanoplasmonic molecular ruler. a, Synthesis process of the Au–DNA nanoconjugate. The 20-nm Au nanoparticle modified with a phosphine surfactant monolayer was enclosed by a layer of synthesized 54-bp dsDNA. A thiol group and the FITC (fluorescein isothiocyanate) fluorophore (as indicated by green star) were synthesized at each end of the dsDNA, respectively. Through the thiol–Au chemistry, the dsDNA was tethered onto the Au nanoparticles. b, The dsDNA contains endonuclease incision sites positioned at 12, 24, 36 and 48 bp from the Au-nanoparticle-tethered end. The fluorescent labelling (FITC) is only for further confirmation of the nuclease reactions, and is not necessary for plasmon resonance measurements. 128

# Detection and identification of proteins using nanoparticle–fluorescent polymer ‘chemical nose’ sensors

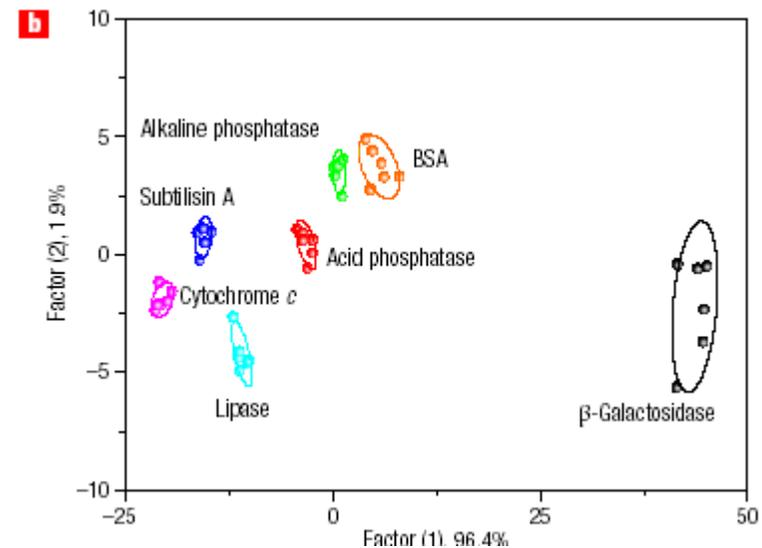

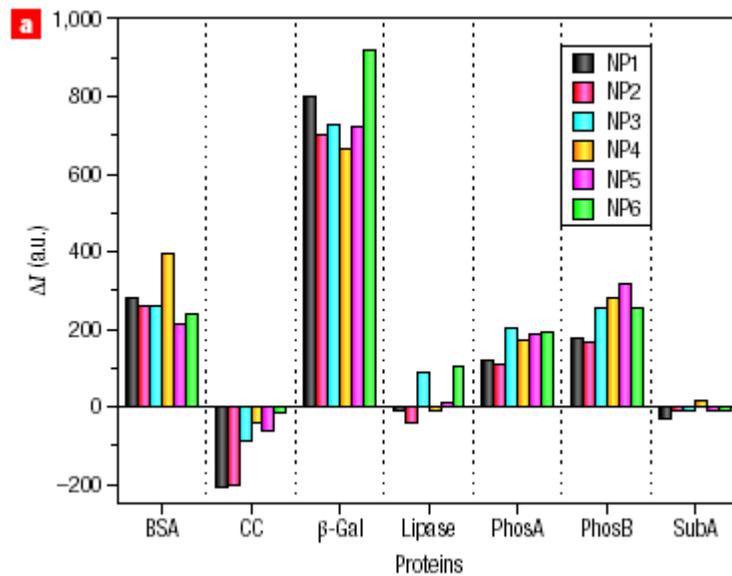

C.-C. YOU, O. R. MIRANDA, B. GIDER<sup>1</sup>, P. S. GHOSH, I.-B. KIM, B. ERDOGAN<sup>1</sup>, S. A. KROVI, U. H. F. BUNZ, VINCENT M. ROTELLO  
nature nanotechnology VOL 2 |MAY 2007 , page 318

**Figure 1** Fluorophore displacement protein sensor array. **a**, Displacement of quenched fluorescent polymer (dark green strips, fluorescence off; light green strips, fluorescence on) by protein analyte (in blue) with concomitant restoration of fluorescence. The particle monolayers feature a hydrophobic core for stability, an oligo(ethylene glycol) layer for biocompatibility, and surface charged residues for interaction with proteins. **b**, Fluorescence pattern generation through differential release of fluorescent polymers from gold nanoparticles. The wells on the microplate contain different nanoparticle–polymer conjugates, and the addition of protein analytes produces a fingerprint for a given protein.

**Figure 2** Structural features of nanoparticles, polymer transducer and target analytes. **a**, Chemical structure of cationic gold nanoparticles (NP1–NP6) and anionic fluorescent polymer PPE-CO<sub>2</sub> ( $m \approx 12$ , where  $m$  refers to the number of repeated units in the polymer). **b**, Surface structural feature and relative size of seven proteins and the nanoparticles used in the sensing study. Colour scheme for the proteins: nonpolar residues (grey), basic residues (blue), acidic residues (red) and polar residues (green).

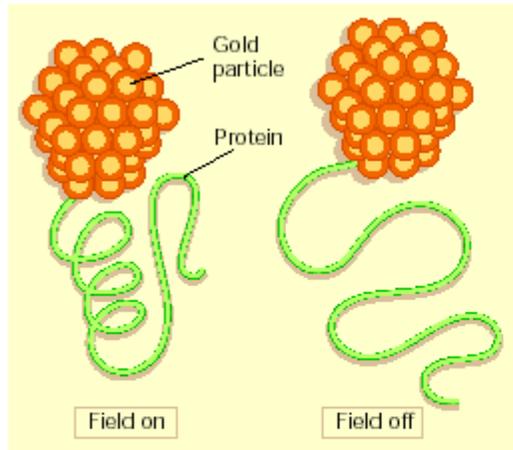

**Figure 4** Array-based sensing of protein analytes at 5  $\mu\text{M}$ . **a**, Fluorescence response ( $\Delta I$ ) patterns of the NP–PPE sensor array (NP1–NP6) against various proteins (CC, cytochrome *c*;  $\beta$ -Gal,  $\beta$ -galactosidase; PhosA, acid phosphatase; PhosB, alkaline phosphatase; SubA, subtilisin A). Each value is an average of six parallel measurements. **b**, Canonical score plot for the first two factors of simplified fluorescence response patterns obtained with NP–PPE assembly arrays against 5  $\mu\text{M}$  proteins. The canonical scores were calculated by LDA for the identification of seven proteins. The 95% confidence ellipses for the individual proteins are also shown.

LDA = linear discriminant analysis

# photothermal therapy

travel as far through living tissue as a magnetic field can. "We wanted something that

Kimberly Hamad-Schifferli (right) hopes to control proteins by attaching tiny gold particles to them — in a radio field the particle heats up, altering the protein's structure and inactivating it.

'nano' word is over-used and over-hyped," says John Ryan, director of the Nanobiotech-

paced activities of daily life in the cell. And for those in the nanosystems alliance, nanotechnology is the best way to get a grip on the many fleeting processes involved. Alliance member Leroy Hood, a molecular biologist at the Institute for Systems Biology in Seattle, predicts that nanotechnology will reveal as much new information about the cell as did the automated DNA sequencer — a device that he invented. "The combination of microfluidics and nanotechnology," Hood asserts, "will transform how biologists do everything." ■
