Myocardial infarction leads to loss of tissue and impairment of cardiac performance. The remaining myocytes are unable to reconstitute the necrotic tissue, and the post-infarcted heart deteriorates with time¹. Injury to a target organ is sensed by distant stem cells, which migrate to the site of damage and undergo alternate stem cell differentiation²⁻⁵; these events promote structural and functional repair⁶⁻⁸. This high degree of stem cell plasticity prompted us to test whether dead myocardium could be restored by transplanting bone marrow cells in infarcted mice. We sorted lineage-negative (Lin⁻) bone marrow cells from transgenic mice expressing enhanced green fluorescent protein⁹ by fluorescence-activated cell sorting on the basis of c-kit expression¹⁰. Shortly after coronary ligation, Lin⁻ c-kit^{POS} cells were injected in the contracting wall bordering the infarct. Here we report that newly formed myocardium occupied 68% of the infarcted portion of the ventricle 9 days after transplanting the bone marrow cells. The developing tissue comprised proliferating myocytes and vascular structures. Our studies indicate that locally delivered bone marrow cells can generate *de novo* myocardium, ameliorating the outcome of coronary artery disease.

Figure 2 Myocardial infarct injected with Lin⁻ c-kit^{POS} cells. Myocardium is regenerating from endocardium (EN) to epicardium (EP). **a**, EGF (green), **b**, cardiac myosin (red), **c**, combination of EGF and myosin (red-green), and propidium iodide stained nuclei (blue). Infarcted tissue (IT) can be seen in the subepicardium. Spared myocytes (SM) can be seen in the subepicardium. Original magnification, $\times 250$ (a-c).

Intracoronary Bone Marrow-Derived Progenitor Cells in Acute Myocardial Infarction

Background: Bone marrow-derived progenitor cells may improve left ventricular function after acute myocardial infarction.

Objective: To evaluate the effects of intracoronary infusion of autologous bone marrow-derived progenitor cells on left ventricular function after acute myocardial infarction.

Design: Randomized, placebo-controlled, multicenter trial.

Setting: 10 centers in Germany.

Participants: 166 patients with acute myocardial infarction.

Measurements and Main Results: At 4 months, the absolute improvement in the global left ventricular ejection fraction (LVEF) was significantly greater in the BMC group than in the placebo group (mean increase, 5.5±7.3% vs 3.0±6.5%; P=0.01).

Randomized, placebo controlled, multicenter trial of intracoronary infusion of BMC after successful PCI for acute myocardial infarction

At 4 months, the absolute improvement in the global left ventricular ejection fraction (LVEF) was significantly greater in the BMC group than in the placebo group (mean increase, 5.5±7.3% vs 3.0±6.5%; P=0.01)

Significant inverse relation between the baseline LVEF and the absolute change in LVEF at 4 months in the BMC group

TOPCARE-CHD

Transcatheter Transplantation of Progenitor Cells after Myocardial Infarction

Background: Transcatheter transplantation of progenitor cells derived from bone marrow (BMC) or cultured bone marrow (CBM) may improve left ventricular function after acute myocardial infarction. The effects of cell transplantation in patients with healed myocardial infarction are unknown.

Objective: To evaluate the effects of transcatheter transplantation of BMC or CBM on left ventricular function in patients with healed myocardial infarction.

Design: Randomized, placebo-controlled, multicenter trial.

Setting: 10 centers in Germany.

Participants: 166 patients with healed myocardial infarction.

Measurements and Main Results: At 4 months, the absolute change in left ventricular ejection fraction was significantly greater in patients receiving BMC (14.2±7.2%) compared with those receiving CBM (12.6±7.2%) (P=0.008). The increase in global LVEF was related to significantly reduced regional contractility in the area targeted by transcatheter infusion of BMC. The crossover plan of the study revealed that transcatheter infusion of BMC was associated with a significant increase in global and regional left ventricular function, regardless of whether patients crossovered from control to BMC or from CBM to BMC.

RESULTS

After an initial pilot trial involving 17 patients, we randomly assigned, on a controlled crossover study, 176 patients with healed myocardial infarction who had had a myocardial infarction at least 3 months previously to receive either an intracoronary (23 patients) or intravenous (153 patients) infusion of BMC (23 patients) into the patent coronary artery supplying the most dysfunctional left ventricular area. The patients in the control group were subsequently randomly assigned to receive CBM or BMC, and the patients who initially received BMC or CBM crossed over to receive CBM or BMC, respectively, at a separate infarction.

CONCLUSIONS

Intracoronary infusion of progenitor cells is safe and feasible in patients with healed myocardial infarction. Transplantation of BMC is associated with moderate but significant improvement in the left ventricular system after 4 months.

No improved LVEF, no reduction of left ventricular end-diastolic volume or infarct size at 6 months; the study was powered to have an 80% chance of detecting a change of 5% in LVEF (smaller effects might have been missed)

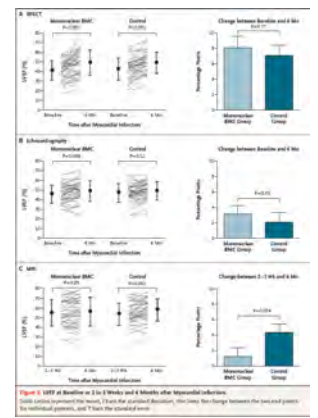

Figure 1. LVEF at Baseline, 6 Months, and 18 Months after Myocardial Infarction. Data are presented as mean ± SD. The primary endpoint (LVEF) was assessed by MRI. The secondary endpoint (LVEF) was assessed by echocardiography. *P < 0.05 between the 2 groups.

Mobilized bone marrow cells repair the infarcted heart, improving function and survival

David D'Amico, Jan Eickholt, Michael Christy, Federico Lippold, Greg Johnson, Federico Quattrone, Bernardo Nadal-Ginard, David M. Bader, Antonello Liati, and Piero Aremini

Attempts to repair myocardial infarcts by transplanting cardiomyocytes or skeletal myoblasts have failed to reconstitute healthy myocardium and coronary vessels integrated structurally and functionally with the remaining viable portion of the ventricular wall. The recently discovered growth and transdifferentiation potential of primitive bone marrow cells (BMC) prompted us, in an earlier study, to inject in the border zone of acute infarcts Lin²-⁺Kit⁺ BMC from syngeneic animals. These BMC differentiated into myocytes and vascular structures, ameliorating the function of the infarcted heart. Two critical determinants seem to be required for the transdifferentiation of primitive BMC: tissue damage and a high level of pluripotent cells. On this basis, we hypothesized here that BMC, mobilized by stem cell factor and granulocyte-colony stimulating factor, would home to the infarcted region, replicate, differentiate, and ultimately promote myocardial repair. We report that, in the presence of an acute myocardial infarct, cytokine-mediated translocation of BMC resulted in a significant degree of tissue regeneration 27 days later. Cytokine-induced cardiac repair decreased mortality by 68%, infarct size by 40%, cavity dilation by 26%, and diastolic stress by 70%. Ejection fraction progressively improved and hemodynamics significantly improved as a consequence of the formation of 15 × 10⁶ new myocytes with arterioles and capillaries connected with the circulation of the unaffected ventricle. In conclusion, mobilization of primitive BMC by cytokines might offer a noninvasive therapeutic strategy for the regeneration of the myocardium lost as a result of ischemic heart disease and, perhaps, other forms of cardiac pathology.

STEMMI

Stem Cell Mobilization Induced by Subcutaneous Granulocyte-Colony Stimulating Factor to Improve Cardiac Regeneration After Acute ST-Elevation Myocardial Infarction

Result of the Double-Blind, Randomized, Placebo-Controlled Stem Cells in Myocardial Infarction (STEMMI) Trial

Klaus Schaeuble, MD, PhD, Erik Bergheim, MD, Yongming Wang, MD, Sam Jaffe, PhD, Hans-Joachim Tebbe, MD, Lars Schaeuble, MD, Hans Erik Johansen, MD, Lars Kubler, MD, Peter Gassler, MD, Axel Kallings, MD

Background—Prior clinical trials of granulocyte-colony stimulating factor (G-CSF) treatment after myocardial infarction have suggested that G-CSF treatment may improve left ventricular function. This randomized, double-blind, placebo-controlled trial aimed to assess the efficacy of subcutaneous G-CSF treatment on left ventricular function in patients with ST-elevation myocardial infarction.

Methods and Results—In a 2-group, parallel, randomized trial, 100 patients were randomly assigned to receive either subcutaneous G-CSF (10 mg/kg daily) or placebo (saline) for 5 days. The primary end point was the change in left ventricular ejection fraction (LVEF) at 6 months. Secondary end points included mortality, infarct size, and left ventricular end-diastolic volume. The trial was powered to detect a 5% increase in LVEF at 6 months. The primary end point was not reached. There was no significant difference in LVEF between the G-CSF and placebo groups at 6 months. There was a significant difference in mortality between the G-CSF and placebo groups at 6 months. There was no significant difference in infarct size or left ventricular end-diastolic volume between the G-CSF and placebo groups at 6 months.

Key Words: granulocyte colony-stimulating factor; myocardial infarction; myocardial regeneration; myocardial infarction

Lost in translation

Kenneth R. Chen

The potential use of stem cells as agents of repair in human disease makes them the subject of high-profile studies. But we should be wary of prematurely pushing laboratory research into clinical practice.

Figure 1. Two strategies used to show that bone marrow stem cells do not take the role of damaged heart cells. (a) Direct injection of donor GFP into the heart. (b) Indirect injection of donor GFP into the circulation. The modification "tag" the cells with GFP, enabling them to be detected in the recipient mouse heart, into which the cells were directly injected. Close inspection of the recipient heart showed that the label could not be detected in heart muscle cells. Similar results were shown by Balsam et al., although the approach was slightly different. Donor bone marrow stem cells were transfused directly into the circulation of recipients. Again, the tag (GFP green fluorescent protein) could not be detected in heart muscle cells of the donor; indeed, the bone marrow cells continued to differentiate into blood cells while in the heart.

Early results of autologous skeletal myoblasts transplantation in patients with severe ischemic heart failure

Howard Leonhardt founded Bioheart in 1999 around a process, Myocell, which involves biopsying a patient's thigh muscle to obtain skeletal myoblasts, culturing them and expanding them over a course of about four weeks, then injecting them back into the heart using a percutaneous injection catheter

Why myoblasts?

- They differentiate into muscle cells capable of active contraction
- They can survive in ischemic scar tissue better than other types of cells
- Contact inhibition prevents them from over-proliferation

Preliminary results:

1st patient implanted in 2001
 15 patients enrolled in Phase I/II study in 2002, with 6 month completed follow-up
 20% average improvement by injecting 150 million cells

ABSTRACT

We report the case of a patient who had undergone injections of myoblasts in an infarct area 16 years before being referred for heart transplantation. The pathological examination of the explanted heart found persisting myotubes embedded in fibrosis. This finding supports the ability of myoblasts to survive in harsh environments, which can make them appealing candidates for transplantation in diseases requiring supply of new myogenic cells. ES cells

Can embryonic stem cells be used for cardiac repair?

Establishment in culture of pluripotent cells from mouse embryos

Evans MJ and Kaufman MH (1981), Nature 292, 154-156

Pluripotency of mouse embryonic stem cells (ES)

ES cells transplanted into the heart develop into a teratoma:

- extensive replacement of the ventricular wall and cavity with tumor, with central necrosis
- Multiple nodules of cartilage (mesodermal) at the interface with host myocardium
- Several poorly differentiated epithelial cells
- Gut epithelium and ciliated respiratory epithelium (endodermal)
- Stratified squamous epithelium (ectodermal)

C. Murry (University of Washington, Seattle)

Stem cell based tissue engineering for myocardial repair

In Italia la materia è regolamentata dalla legge 40 del 2004

- Max 3 embrioni alla volta, tutti da impiantare
 - ridotta efficienza di gravidanza per ciclo ormonale, necessità di ricorrere a più cicli
 - impossibilità di ricavare nuove linee ES
- Divieto di utilizzo degli embrioni sovranumerari prodotti in passato (circa 30,000 embrioni intoccabili in Italia)
 - però è possibile usare cellule ES ottenute in altri paesi

Giugno 2005: 4 referendum per abrogare parte della L40

90% dei votanti a favore dell'abrogazione ma solo 26% di affluenza ai seggi

Il problema principale legato alle cellule staminali embrionali non e' pero' di natura scientifica ma di natura metafisica ed e' legato al concetto di inizio della vita umana

Are we destroying life?

- The potential to treat so many diseases far outweighs the 'cost' of having to destroy these embryos.
- An embryo is not life itself, it just has the potential to become one.
- Blastocysts are just a collection of cells, which have not differentiated into specific types. Making them about as 'human' as skin cells.
- It is estimated that about 18% of zygotes do not implant after conception, making this number far more than the number of embryos used for stem cell research.
- It must be noted that that only unused embryos are used for stem cell research.

Can ES cells be obtained without egg fertilization?

Figure 2 Cloned frogs. These 19 identical male albino frogs were prepared by nuclear transplantation into unfertilized eggs of the dark green female frog³³. (Male frogs are about half the size of females.)

In vitro differentiation into all three germ layers.

Induction of pluripotent stem cells from mouse embryonic or adult fibroblasts by introducing four factors, **Oct3/4**, **Sox2**, **c-Myc**, and **Klf4** in the FBX15 locus, under ES cell culture conditions.

These cells, which were designated iPS (induced pluripotent stem) cells, exhibit the morphology and growth properties of ES cells and express ES cell marker genes.

1- Subcutaneous transplantation of iPS cells into nude mice resulted in tumors containing a variety of tissues from all three germ layers.

2- Following injection into blastocysts, iPS cells contributed to mouse embryonic development, but embryos failed to develop beyond mid-gestation stage.

Derivation and cardiomyocyte differentiation of induced pluripotent stem cells from heart failure patients

Abstract

Aims Myocardial cell replacement therapies are hampered by a paucity of sources for human cardiomyocytes and by the expected immune rejection of allogeneic cell grafts. The ability to derive patient-specific human-induced pluripotent stem cells (iPSCs) may provide a solution to these challenges. We aimed to derive hiPSCs from heart failure (HF) patients, to induce their cardiomyocyte differentiation, to characterize the generated hiPSC-derived cardiomyocytes (hiPSC-CMs), and to evaluate their ability to integrate with pre-existing cardiac tissue.

Methods and results Dermal fibroblasts from two HF patients were reprogrammed by retroviral delivery of Oct4, Sox2, and Klf4 by using an excisable polycistronic lentiviral vector. The resulting HF-hiPSCs displayed adequate reprogramming properties and could be induced to differentiate into cardiomyocytes with the same efficiency as control hiPSCs (derived from human foreskin fibroblasts). Gene expression and immunostaining studies confirmed the cardiomyocyte phenotype of the differentiating HF-hiPSC-CMs. Multi-electrode array recordings revealed the development of a functional cardiac syncytium and adequate chronotropic responses to adrenergic and cholinergic stimulation. Next, functional integration and synchronized electrical activities were demonstrated between hiPSC-CMs and neonatal rat cardiomyocytes in co-culture studies. Finally, in vivo transplantation studies in the rat heart revealed the ability of the HF-hiPSC-CMs to engraft, survive, and structurally integrate with host cardiomyocytes.

HEART DISEASE Scientists Turn Human Skin Cells Into Healthy Heart Cells

Cardiac stem cells in patients with ischaemic cardiomyopathy (SCPIO): initial results of a randomised phase 1 trial

Antonio Rossi, et al. (Chicago, Illinois) *N Engl J Med* 2014; 370: 1855-65. doi:10.1056/NEJMoa1310529

Summary
Background: c-kit-positive, lineage-negative cardiac stem cells (CSCs) improve post-infarction left ventricular (LV) dysfunction when administered to animals. We conducted a phase 1 trial (SCPIO) to evaluate the safety of intracoronary injection of autologous CSCs for the treatment of heart failure resulting from ischemic heart disease.

Methods: The stage 1 of the SCPIO trial, patients with post-infarction LV dysfunction (ejection fraction [EF] <40%) before coronary artery bypass grafting were consecutively enrolled in the treatment and control groups. In stage 1, patients were randomly assigned to the treatment or control group in a 2:1 ratio by use of a computer-generated block randomization scheme. 1 million autologous CSCs were administered by transcatheter infusion at a mean of 113 days (SE 4) after surgery; controls were not given any treatment. Although the study was open label, the echocardiographic analyses were masked to group assignment. The primary endpoint was the short-term safety of CSCs and the secondary endpoint was efficacy. A per protocol analysis was used. This study is registered with ClinicalTrials.gov, number NCT01367445.

Results: This study is still in progress. 36 patients were assigned to the treatment group and seven to the control group on CSC-related adverse effects were reported. In 14 CSC-treated patients who were analyzed, LV EF increased from 39.5% (SE 1.9) before CSC infusion to 35.5% (SE 2.4) at 4 months after infusion (p=0.007). By contrast, in seven control patients, during the corresponding time interval, LV EF did not change (39.5% [SE 1.2] at 4 months after CABG to 38.7% [SE 3.4] at 8 months after CABG). Importantly, the salutatory effects of CSCs were even more pronounced at 2 years in eight patients (eg, LV EF increased by 3.2; 95% confidence interval [CI], 1.6 to 4.8; p=0.0002). In the seven treated patients in whom cardiac MRI could be done, infarct size decreased from 32.4 g (SE 7.7; 24%) at 4 months post-SCPIO to 9.5 g (SE 5.3; 30%) at 1 year post-SCPIO.

Interpretation: These initial results in patients are very encouraging. They suggest that intracoronary infusion of autologous CSCs is effective in improving LV systolic function and reducing infarct size in patients with heart failure after myocardial infarction, and warrant further, larger, phase 2 studies.

Intracoronary cardiosphere-derived cells for heart regeneration after myocardial infarction (CADUCEUS): a prospective, randomised phase 1 trial

Antonio Rossi, et al. (Chicago, Illinois) *N Engl J Med* 2014; 370: 1855-65. doi:10.1056/NEJMoa1310529

Summary
Background: Cardiosphere-derived cells (CDCs) reduce scar size after myocardial infarction, increase viable myocardium, and boost cardiac function in preclinical models. We aimed to assess safety of such an approach in patients with left ventricular dysfunction after myocardial infarction.

Methods: In this prospective, randomised, CADUCEUS trial, we enrolled patients 3-6 weeks after transcatheter infarction with left ventricular ejection fraction of 35-50% or less medical therapy in the USA. An independent data-monitoring committee randomly allocated patients to a 2:1 ratio to receive CDCs or standard care. The patients assigned to receive CDCs, autologous cells grown from myocardial biopsy specimens, were infused into the infarcted artery. In a controlled, open-label, randomised trial, the primary endpoint was proportion of patients at 8 months who died due to cardiovascular mortality. The primary endpoint was proportion of patients at 8 months who died due to cardiovascular mortality. Secondary endpoints included the number of patients who had myocardial infarction after infarction, new or recurrent myocardial infarction, or death from any cause. All patients were followed up for 8 months. We also assessed postoperative efficacy, measured by MRI at 8 months. This analysis was masked to group assignment. This study is registered with ClinicalTrials.gov, NCT01367445.

Results: Between May 1, 2008, and Dec 16, 2010, we randomly allocated 11 eligible participants of whom 21 were included in a per-protocol analysis of CDC group and eight in standard of care. Mean baseline left ventricular ejection fraction (LVEF) was 39% (SD 12) and was increased 24% (SE 2) of left ventricular mass. Single samples randomised per-protocol analyses for death due to cardiovascular mortality were reported within 24 h of CDC infusion. In 4 months, no patients had died. Discharged cardiac biomarkers, or MRI in either group. Four patients (19%) in the CDC group had recurrent myocardial infarction compared with one control (25% per 100). Compared with controls, at 8 months, MRI analyses showed that CDCs showed reduction in scar mass (p=0.001), increase in viable heart mass (p=0.01) and regional contractility (p=0.01), and regional stroke work (p=0.01). However, changes in myocardial infarction, ventricular volume, and LVEF did not differ between groups by 8 months.

Interpretation: We show intracoronary infusion of autologous CDCs after myocardial infarction can, according to the hypothesis of such therapy in phase 2 study. The anticipated increases were noted in viable myocardium, which are associated with favourable improvement of clinical outcomes.

Funding: US National Heart Lung and Blood Institute and Center for Heart and Lung Research.

Harvard and the Brigham call for more than 30 retractions of cardiac stem cell research

STATNEWS, OCTOBER 14, 2018

Harvard Medical School and Brigham and Women's Hospital have recommended that 31 papers from a former lab director be retracted from medical journals.

The papers from the lab of Dr. Piero Anversa, who studied cardiac stem cells, "included falsified and/or fabricated data"

Anversa has previously corrected 8 of his papers, many for failures to disclose conflicts of interest. He "practically invented the field of cardiac stem cell therapy when he first reported that cardiac cells were capable of regeneration," Cardiobrief and MedPage Today wrote about him last year.

Anversa's work was based on the idea that the heart contains stem cells that could regenerate cardiac muscle. He and his colleagues claimed that they had identified such cells, known as c-kit cells. When various research teams tried to reproduce the results, however, they failed. Scientists have tried to inject c-kit cells into damaged hearts, with mixed results at best.

"For 10 years, he ran everything," said Jeffery Molkentin, a researcher at Cincinnati Children's whose lab was among the first to question the basis of Anversa's results in a 2014 paper in Nature. "It really is a relief that this has been corrected. I think this is good for everybody."

"There are no stem cells in the heart. Quit trying to publish those results."

JEFFERY MOLKENTIN, CINCINNATI CHILDREN'S

Still, he said, a small number of researchers continue to publish findings that agree with Anversa's. "Maybe these 31 retractions will keep pushing the pendulum a little further to the right and these people will slowly start to back off even more," he said. "It's just discouraging when you see these papers keep popping up," Molkentin said. "There are no stem cells in the heart. Quit trying to publish those results."

c-kit⁺ cells minimally contribute cardiomyocytes to the heart

Jop H. van Berlet^{1,2*}, Omur Kanisickak^{1*}, Marjorie Maillet¹, Ronald J. Vagnozzi¹, Jason Karch¹, Suh-Chin J. Lin¹, Ryan C. Middleton³, Eduardo Marbán¹ & Jeffery D. Molkentin^{1,4}

If and how the heart regenerates after an injury event is highly debated. c-kit-expressing cardiac progenitor cells have been reported as the primary source for generation of new myocardium after injury. Here we generated two genetic approaches in mice to examine whether endogenous c-kit⁺ cells contribute differentiated cardiomyocytes to the heart during development, with aging or after injury in adulthood. A complementary DNA encoding either Cre recombinase or a tamoxifen-inducible MerCreMer chimera protein was targeted to the Kit locus in mice and then bred with reporter lines to permanently mark cell lineage. Endogenous c-kit⁺ cells did produce new cardiomyocytes within the heart, although at a percentage of approximately 0.03 or less; and if a preponderance towards cellular fusion is considered, the percentage falls to below approximately 0.008. By contrast, c-kit⁺ cells amply generated cardiac endothelial cells. Thus, endogenous c-kit⁺ cells can generate cardiomyocytes within the heart, although probably at a functionally insignificant level.

Braggadacio, information control, and fear: Life inside a Brigham stem cell lab under investigation

Regular readers of Retraction Watch will note the recent news regarding the work conducted in the laboratory of **Piero Anversa** at Brigham and Women's Hospital, a Harvard Medical School affiliate. In the early 2000s, his laboratory published a series of papers regarding the regenerative qualities of bone marrow-derived and cardio-resident "stem cells." Those initial findings, as well as the research conducted since those early studies, have always been surrounded by controversy, as many have been unsuccessful in efforts to replicate their results. Controversy among competitors is not uncommon in our profession, but this particular one has blossomed into a formal investigation of their findings, and has, to date, led to the retraction of one paper and an expression of concern about another.

The "Science" I think that most scientists, perhaps with the exception of the most lucky or most dishonest, have personal experience with failure in science—experiments that are unreproducible, hypotheses that are fundamentally incorrect. Generally, we sigh, we alter hypotheses, we develop new methods, we move on. It is the data that should guide the science. In the Anversa group, a model with much less intellectual flexibility was applied. The "hypothesis" was that c-kit (cd117) positive cells in the heart (or bone marrow if you read their earlier studies) were cardiac progenitors that could: 1) repair a scarred heart post-myocardial infarction, and 2) supply the cells necessary for cardiomyocyte turnover in the normal heart. This central theme was that which supplied the lab with upwards of \$50 million worth of public funding over a decade, a number which would be much higher if one considers collaborating labs that worked on related subjects.

In theory, this hypothesis would be elegant in its simplicity and amenable to testing in current model systems. In practice, all data that did not point to the "truth" of the hypothesis were considered wrong, and experiments which would definitively show if this hypothesis was incorrect were never performed (lineage tracing e.g.). Further, controls that suggested that the data might be artifactual were ignored or not conducted. However, I challenge the readers to determine any of this information from the published manuscripts. So how does this slip through the cracks for years? The fault for this can likely be attributed to multiple sources although a conspicuous lack of stringency in the peer review process of the journals in which they were published come to mind. Beyond the science, ironically, a certain braggadocio also existed surrounding this hypothesis. Anyone who attended the pertinent sessions at the American Heart Association Scientific Sessions could attest to this. In essence, to Dr. Anversa all investigators who questioned the hypothesis were "ignorant," a word he used frequently at lab meetings. For one within the group to dare question the central hypothesis, or the methods used to support it, was a quick ticket to dismissal from your position.

Information Segregation + Machiavellian Principles = Successful Lab The day to day operation of the lab was conducted under a severe information embargo. The lab had Piero Anversa at the head with group leaders Annarosa Leri, Jan Kajstura and Marcello Rota immediately supervising experimentation. Below that was a group of around 25 instructors, research fellows, graduate students and technicians. Information flowed one way, which was up, and conversation between working groups was generally discouraged and often forbidden. Rare data left one's hands, went to the immediate superior (one of the three named above) and the next time it was seen would be in a manuscript or grant. What happened to that data in the intervening period is unclear.

A side effect of this information embargo was the limitation of the average worker to determine what was really going on in a research project. It would also effectively limit the ability of an average worker to make allegations regarding specific data/experiments, a requirement for a formal investigation. The general game plan of the lab was to use two methods to control the workforce: Reward those who would play along and create a general environment of fear for everyone else. The incentive was upward mobility within the lab should you stick to message. As ridiculous as it sounds to the average academic scientist, I was personally promised money and fame should I continue to perform the type of work they desired there. There was also the draw of financial security/job stability that comes with working in a very well-funded lab. On the other hand, I am not overstating when I say that there was a pervasive feeling of fear in the laboratory. Although individually tailored stated and unstated threats were present for lab members, the plight of many of us who were international fellows was especially harrowing. Many were technically and educationally underqualified compared to what might be considered average research fellows in the United States. Many also originated in Italy where Dr. Anversa continues to wield considerable influence over biomedical research. This combination of being undesirable to many other labs should they leave their position due to lack of experience/training, dependent upon employment for U.S. visa status, and under constant threat of career suicide in your home country should you leave, was enough to make many people play along.

Even so, I witnessed several people question the findings during their time in the lab. These people and working groups were subsequently fired or resigned. I would like to note that this lab is not unique in this type of exploitative practice, but that does not make it ethically sound and certainly does not create an environment for creative, collaborative, or honest science. **Lessons Learned** So what, if anything, did I learn from spending a period of my life in my scientific nightmare? The conditions I have written about are not unique, although the particulars of how the misconduct happened may be. The simplest explanation is that, in spite of the efforts of ethical watchdogs, these are behaviors that science is selecting for with its current funding and publication mechanisms. I was glad to learn of the investigation regarding this lab but without vigilance and alterations to current structures, newer, more careful versions of Piero Anversa will undoubtedly move in to take his place.

Direct regeneration

Anversa published at least 55 papers that listed Harvard as an affiliation. In 2014, a former research fellow described an atmosphere of fear and information control in his lab.

Anversa, who according to publications was most recently affiliated with the Cardiocentro Ticino and University of Zurich, could not be reached for comment. An email to his address at Cardiocentro Ticino bounced back. A number of Anversa's co-authors either did not immediately respond to a request for comment, or declined.

Anversa was born in Parma, Italy, in 1940 and received his medical degree from the University of Parma in 1965. He gained prominence as a stem-cell researcher at New York Medical College in Valhalla, N.Y., where he worked before moving to Harvard Medical School and the Brigham in 2007. Anversa became a full professor in 2010.

Throughout his career, Anversa has received several commendations, including a research achievement award from the American Heart Association, which in 2004 also named him a "distinguished scientist." Although journals often act on retraction recommendations by universities, they do not always do so, and it sometimes takes a while. Journals retract roughly 1,400 scholarly papers each year, out of some 3 million total publications. Anversa's total would put him in the top 20 list of scientists with the most retractions in the world. The 10 scientists worldwide with the most retracted papers have at least 39, and in one case — Japanese anesthesiologist Yoshitaka Fujii — 183 such articles. So what do the calls for retraction mean for cardiology?

"What seems obvious to me is a need for transparency," Yale cardiologist Dr. Harlan Krumholz told STAT and Retraction Watch. "The scientific community needs to know what was found, why papers were retracted, and what is recommended with regard to his work going forward. Also, what has happened to work that was based on his work. Without this knowledge it is hard to know what it means."

Exosomes secreted by cardiosphere-derived cells reduce scarring, attenuate adverse remodeling, and improve function in acute and chronic porcine myocardial infarction

Romain Gallet^{1,2†}, James Dawkins^{1†}, Jackelyn Valle¹, Eli Simisola¹, Geoffrey de Couto¹, Ryan Middleton¹, Eleni Tselou¹, Daniel Luthringer¹, Michelle Kreke^{1,3}, Rachel R. Smith¹, Linda Marbán^{1,3}, Bijan Ghaleh¹, and Eduardo Marbán^{1*}

Exosomes (CAP-2003)

CAP-2003 represents exosomes isolated from the company's proprietary cardiosphere-derived cells (CDCs), and is being developed as a next-generation therapeutic platform in regenerative medicine. Exosomes are nano-sized, membrane-enclosed vesicles, or "bubbles" that are secreted by cells and contain bioactive molecules, including proteins, RNAs and microRNAs. They act as messengers to regulate the functions of neighboring cells, and pre-clinical research has shown that exogenously-administered exosomes can direct or, in some cases, re-direct cellular activity, supporting their therapeutic potential. Their size, ease of crossing cell membranes, and ability to communicate in native cellular language makes them an exciting class of potential therapeutic agents. CAP-2003 consists of exosomes secreted by CDCs, and is believed to mediate many of the effects that are observed with these cells, including anti-inflammatory, anti-angiogenic, anti-apoptotic, and anti-fibrotic effects. Capricor is currently conducting pre-clinical studies to explore the possible therapeutic benefits that exosomes may possess, with a focus on ophthalmologic, dermatologic and oncologic disease. Capricor expects to initially develop CAP-2003 for ocular graft-versus-host disease. CSMC has granted Capricor worldwide rights to its CDC Exosome technology under an exclusive license agreement with Cedars-Sinai Medical Center.

Regenerative responses in urodeles

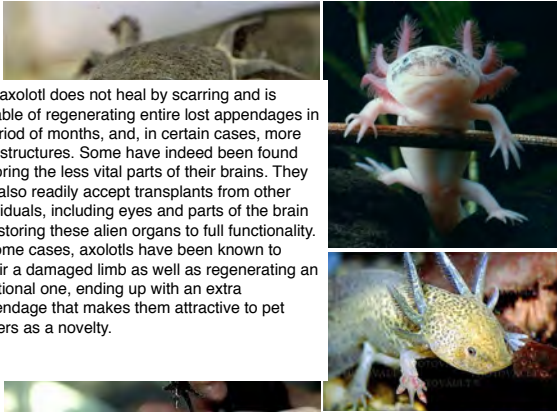

Regeneration might be a primordial attribute of metazoan that has been lost subsequently for reasons that are not yet understood

An adult newt can regenerate:

- Jaws
- Lens
- Retina
- Large sections of the heart
- Limbs
- Tail

Regenerative potential of *Ambystoma mexicanum* (Axolotl)

The axolotl does not heal by scarring and is capable of regenerating entire lost appendages in a period of months, and, in certain cases, more vital structures. Some have indeed been found restoring the less vital parts of their brains. They can also readily accept transplants from other individuals, including eyes and parts of the brain—restoring these alien organs to full functionality. In some cases, axolotls have been known to repair a damaged limb as well as regenerating an additional one, ending up with an extra appendage that makes them attractive to pet owners as a novelty.

Regenerative potential of *Ambystoma mexicanum* (Axolotl)

Several species other than mammals regenerate the heart

Heart Regeneration in Zebrafish

Kenneth D. Poss,¹ Lindsay G. Wilson, Mark T. Keating²

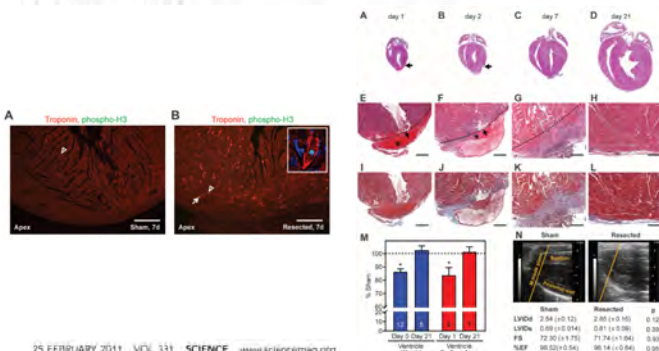

Cardiac injury in mammals and amphibians typically leads to scarring, with minimal regeneration of heart muscle. Here, we demonstrate that surgically that zebrafish fully regenerate hearts within 2 weeks of 20% ventricular resection. Regeneration occurs through robust proliferation of sarcomeres located at the leading, epicardial edge of the new myocardium. The hearts of zebrafish with mutations in the *H9cN1* embryonic checkpoint kinase, a critical cell cycle regulator, failed to regenerate and formed scars. Thus, injury-induced sarcomere proliferation in zebrafish can overcome scar formation, allowing cardiac muscle regeneration. These findings indicate that zebrafish will be useful for genetically dissecting the molecular mechanisms of cardiac regeneration.

New Hypotheses in Clinical Medicine

Functional Recovery of a Human Neonatal Heart After Severe Myocardial Infarction

Bernhard J. Haubner,^{*} Johanna Schneider,^{*} Ulrich Schweigmann, Thomas Schuetz, Wolfgang Dichtl, Corinna Velik-Salchner, Joerg-I. Stein, Josef M. Penninger

Rationale: Cardiac remodeling and subsequent heart failure remain critical issues after myocardial infarction despite improved treatment and reperfusion strategies. Recently, cardiac regeneration has been demonstrated in fish and newborn mice after apex resection or cardiac infarction. Two key issues remain to translate findings in model organisms to future therapies in humans: what is the mechanism and can cardiac regeneration indeed occur in newborn humans?

Objective: To assess whether human neonatal hearts can functionally recover after myocardial infarction.

Methods and Results: Here, we report the case of a newborn child having a severe myocardial infarction due to coronary artery occlusion. The child developed massive cardiac damage as defined by serum markers for cardiomyocyte cell death, electrocardiograms, echocardiography, and cardiac angiography. Remarkably, within weeks after the initial ischemic insult, we observed functional cardiac recovery, which translated into long-term normal heart function.

Conclusions: These data indicate that, similar to neonatal rodents, newborn humans might have the intrinsic capacity to repair myocardial damage and completely recover cardiac function. (*Circ Res.* 2016;118:216-221. DOI: 10.1161/CIRCRESAHA.115.307017.)

Key Words: angiography ■ cell death ■ heart failure ■ myocardial infarction ■ regeneration

Clinical case

- Boy born at the end of 39th week, uneventful labor, umbilical arterial blood ok
- After birth severe cyanosis, reduced oxygen saturation
- ECG: signs of acute ischemia
- Echocardiography: severe LV dysfunction
- Increased BNP, Troponin T and CK
- Coronary angiography

Haubner et al., Circulation Research 2016

- Thrombolysis at 28 hours from first symptoms

LAD re-opening after 3 days
 Persisting myocardial damage evident at echocardiography, ECG and blood markers
 Diagnosis: LAD occlusion for >20 hours, massive MI

MCQ: Outcome of the patient?

1. Complete recovery at 45 days
2. Persisting signs of cardiac dysfunction at repeated follow-up
3. Heart failure at 1 year
4. Death at 2 months

Carbon dating to assess the physiological turnover of human cells

After the Second World War, tests of nuclear bombs spewed carbon-14 pollution into the atmosphere. This isotope was incorporated into plants and the people who consumed them. After above-ground tests were stopped in 1963, levels of the isotope started to fall. The ¹⁴C in a cell's DNA corresponds to the amount of the isotope in the atmosphere at the time it was dividing, providing a way to date a cell's birth.

miR-590 and miR-199a preserve myocardial function after MI

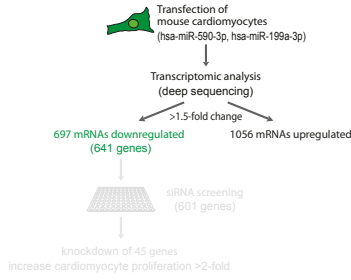

miR-590 and miR-199a markedly reduce infarct size

Eulalio et al. 2012. Nature 492, 376

Mechanisms?

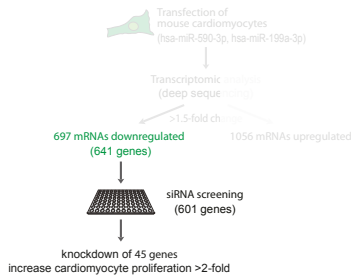

Identification of miR-590-3p and miR-199a-3p target genes

Among the 641 genes downregulated by miR-590-3 and miR-199a-3p there are:

- Myomesin 1 (Myom1)
- Myomesin 2 (Myom2)
- Myosin light polypeptide 4 (Myl4)
- Nebulin-related anchoring protein (Nrap)
- Myosin IB (Myo1b)
- Titin (Ttn)
- Troponin T1, skeletal slow (Tnnt1)
- Troponin T2 cardiac (Tnnt2)
- Cofilin2 (Cofilin2)
- Dynamin1-like (Dnm1l)
- Ankyrin repeat domain 52 (Ankrd52)
- Nebulette (Nbl)

Hippo pathway deficiency reverses systolic heart failure after infarction

John H. Leach¹, Todd Heather², Min Zhang^{2,4}, Malobis Rathnum², Yuka Morikawa², Matthew C. Hill², Ana Segura², James I. Wilkins² & James F. Martin^{1,2,4,5}

Mammalian organs vary widely in regenerative capacity. Poorly regenerative organs, such as the heart are particularly vulnerable to organ failure. Once established, heart failure commonly results in mortality¹. The Hippo pathway, a kinase cascade that prevents adult cardiomyocyte proliferation and regeneration², is upregulated in human heart failure. Here we show that deletion of the Hippo pathway component Salvador (Salv) in mouse hearts with established ischaemic heart failure after myocardial infarction induces a reparative genetic program with increased scar border vascularity, reduced fibrosis, and recovery of pumping function compared with controls. Using translating ribosomal affinity purification, we isolate cardiomyocyte-specific translating messenger RNA. Hippo-deficient cardiomyocytes have increased expression of proliferative genes and stress response genes, such as the mitochondrial quality control gene, *Park2*. Genetic studies indicate that *Park2* is essential for heart repair, suggesting a requirement for mitochondrial quality control in regenerating myocardium. Gene therapy with a virus encoding *Salv* short hairpin RNA improves heart function when delivered at the time of infarct or after ischaemic heart failure following myocardial infarction was established. Our findings indicate that the failing heart has a previously unrecognized regenerative capacity involving more than cardiomyocyte renewal.

In vivo reprogramming of murine cardiac fibroblasts into induced cardiomyocytes

Li Qian^{1,2,3}, Yu Huang^{1,2,3}, C. Ian Spencer^{1,2,3}, Amy Foley^{1,2,3}, Vasanth Vedantham^{1,4,5}, Lei Liu^{1,2,3}, Simon J. Conway⁶, Ji-Dong Fu^{1,2,3} & Deepak Srivastava^{1,2,3}

The reprogramming of adult cells into pluripotent cells or directly into alternative adult cell types holds great promise for regenerative medicine. We reported previously that cardiac fibroblasts, which represent 50% of the cells in the mammalian heart, can be directly reprogrammed to adult cardiomyocyte-like cells *in vitro* by the addition of Gata4, MeZc and Tbx5 (GMT). Here we use genetic lineage tracing to show that resident non-myocytes in the murine heart can be reprogrammed into cardiomyocyte-like cells *in vivo* by local delivery of GMT after coronary ligation. Induced cardiomyocytes became binucleate, assembled sarcomeres and had cardiomyocyte-like gene expression. Analysis of single cells revealed ventricular cardiomyocyte-like action potentials, beating upon electrical stimulation, and evidence of electrical coupling. *In vivo* delivery of GMT decreased infarct size and modestly attenuated cardiac dysfunction up to 3 months after coronary ligation. Delivery of the pro-angiogenic and fibroblast-activating peptide, thymosin β_4 , along with GMT, resulted in further improvements in scar area and cardiac function. These findings demonstrate that cardiac fibroblasts can be reprogrammed into cardiomyocyte-like cells in their native environment for potential regenerative purposes.
