Department of Engineering & Architecture

University of Trieste

Agenda

- ◆ Short cut methods introduction
- ◆ Fenske equation
- ◆ Underwood equations
- ◆ Gilliland correlation method

Short cut methods

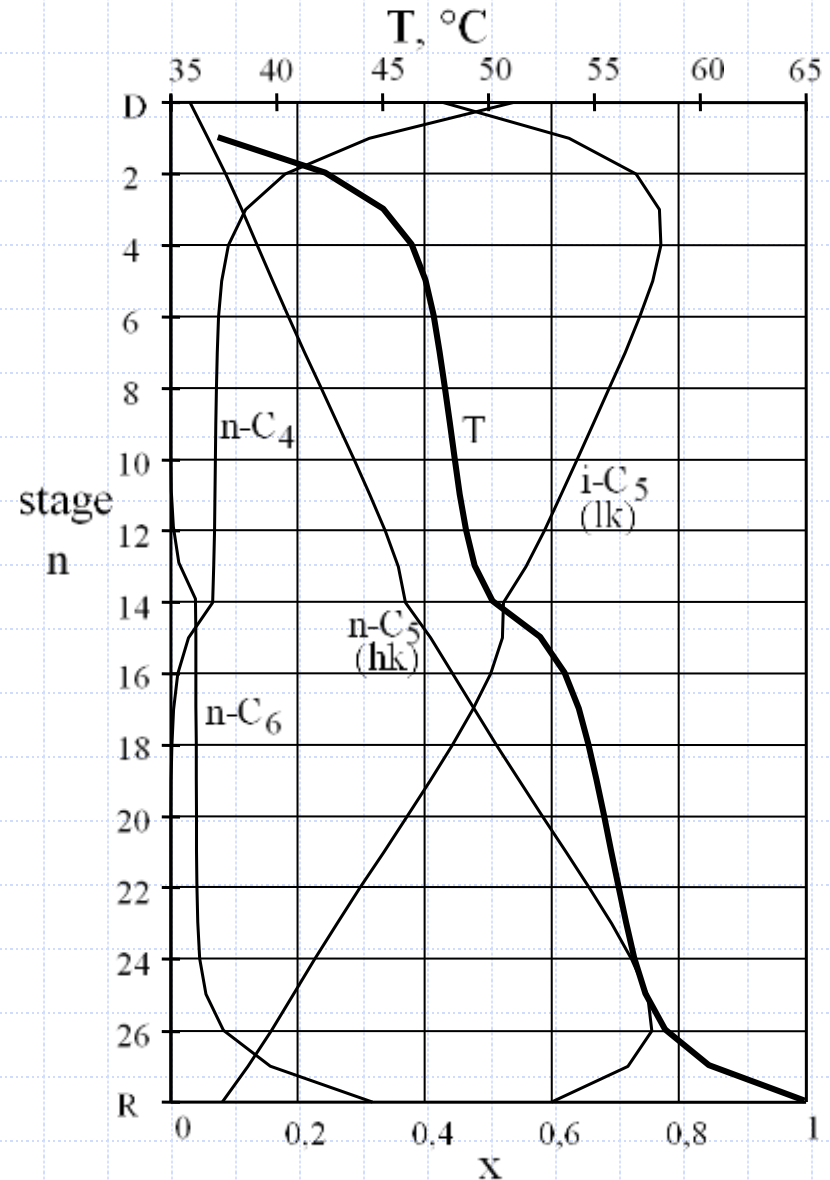

- ◆ In the past, when simulators were not available, different approximate methods were developed.
- ◆ The most relevant is the Fenske-Underwood-Gilliland that combines:
 - Underwood equation for the minimum reflux estimation;
 - Fenske equation for the minimum number of ideal stages estimation;
 - Gilliland correlation for the estimation of the number of ideal stages as a function of reflux ratio and the minimum number of ideal stages

Short cut methods

- ◆ Some assumptions are necessary
 - constant relative volatility in the column
 - constant molar flow rates in the two column sections
- ◆ Short cut methods are based on key components
 - Components that are present in both distillate and residual
 - Light key component is the lightest component that is present in the residue in appreciable concentration
 - Heavy key component is heaviest component that is present in the distillate in appreciable concentration
- ◆ Short cut methods are not much used today
- ◆ The **DSTWU** distillation package in Aspen Plus uses the **Winn-Underwood-Gilliland** short-cut methods and correlation.

Temperature and concentration profiles in the column

- ◆ Distillation of a 4 component mixture:
 - n-C₄, i-C₅, n-C₅, n-C₆
- ◆ Temperature always raise from top to bottom
- ◆ Composition profiles of intermediate components have a maximum
- ◆ Non-key components are separated in few stages and they behave as inert in the other stages

MCD Short-Cut Methods – Limiting Conditions

- ◆ MCD short-cut methods are based upon the limiting conditions for a distillation column:

Reflux Ratio	L/V	L/D	N
Total	$(L/V)_{\max} = 1$	∞	N_{\min}
Actual	L/V	L/D	N
Minimum	$(L/V)_{\min}$	$(L/D)_{\min}$	$N_{\max} = \infty$

- ◆ The actual or operating reflux ratio will lie between the total and minimum reflux ratios – $(L/V)_{\min} < L/V < 1$.
- ◆ The operating reflux ratio, L/D, is often specified as a multiple of the minimum reflux ratio, $(L/D)_{\min}$, e.g.,

$$L/D = 2 \cdot (L/D)_{\min}$$

Fenske (Winn) Equation – N_{\min}

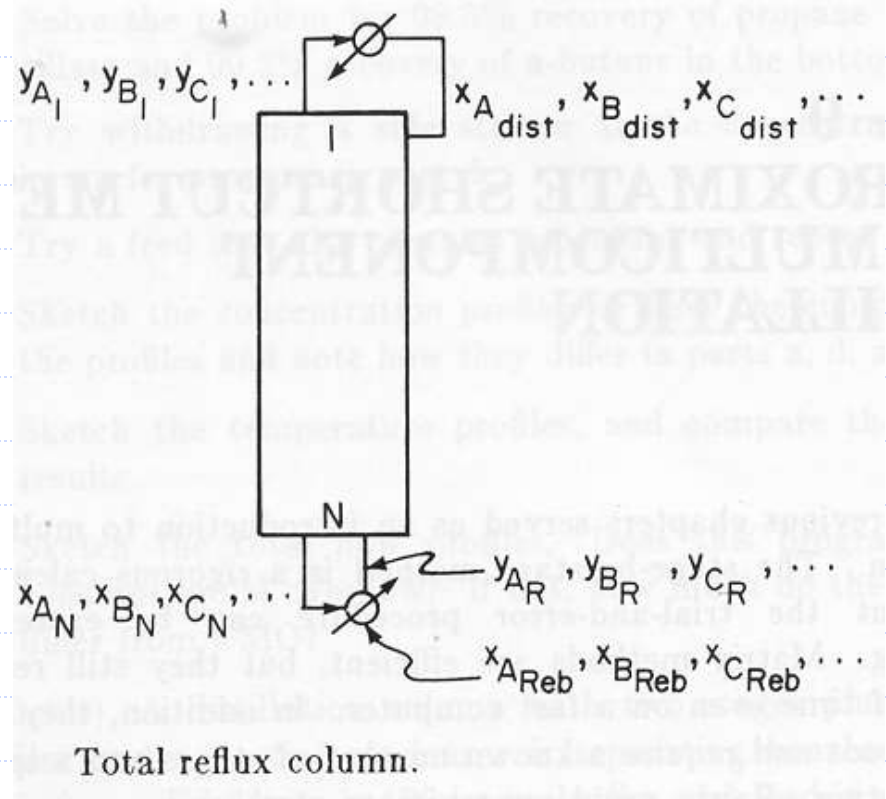

- ◆ While at times we cannot obtain a rigorous solution for complex systems, one can often obtain **rigorous solutions for complex systems at limiting conditions.**
 - One such limiting condition for multi-component systems is the solution **for N_{\min} at total reflux.** This solution is known as the Fenske equation or **Fenske method.**

Fenske (Winn) Equation – Derivation

- While we cannot define a relative volatility for multi-component systems directly, we can begin with defining a relative volatility for component i with respect to a reference component in the multi-component system:

$$\alpha_{i-ref} = \frac{K_i}{K_{ref}} = \left(\frac{y_i}{x_i} \right) / \left(\frac{y_{ref}}{x_{ref}} \right)$$

$$\left(\frac{y_i}{y_{ref}} \right) = \alpha_{i-ref} \left(\frac{x_i}{x_{ref}} \right)$$

Fenske (Winn) Equation – Derivation

- ◆ For a column at total reflux starting at the bottom of the column (the reboiler), we can write :

$$\left(\frac{y_i}{y_{ref}}\right)_{bot} = (\alpha_{i-ref})_{bot} \left(\frac{x_i}{x_{ref}}\right)_{bot}$$

- ◆ For total reflux, we have, $y_{i, bot} = x_{i, N}$ $y_{ref, bot} = x_{ref, N}$
 - where N is the Nth stage at the bottom of the column above the reboiler

- ◆ Substituting these relationships into the previous equation yields

$$\left(\frac{x_i}{x_{ref}}\right)_N = (\alpha_{i-ref})_{bot} \left(\frac{x_i}{x_{ref}}\right)_{bot}$$

- ◆ Similarly, if we step up the column to the N-1 stage, we have

$$\left(\frac{x_i}{x_{ref}}\right)_{N-1} = (\alpha_{i-ref})_N \left(\frac{x_i}{x_{ref}}\right)_N$$

- ◆ Eqs. above can be combined to give

$$\left(\frac{x_i}{x_{ref}}\right)_{N-1} = (\alpha_{i-ref})_N (\alpha_{i-ref})_{bot} \left(\frac{x_i}{x_{ref}}\right)_{bot}$$

Fenske (Winn) Equation – Derivation

- ◆ If we continue to move up the column we obtain to the top of the column (the condenser) or distillate, we obtain

$$\left(\frac{x_i}{x_{ref}}\right)_{dist} = (\alpha_{i-ref})_1 (\alpha_{i-ref})_2 (\alpha_{i-ref})_3 \dots (\alpha_{i-ref})_{N-1} (\alpha_{i-ref})_N (\alpha_{i-ref})_{bot} \left(\frac{x_i}{x_{ref}}\right)_{bot}$$

- ◆ Defining α_{i-ref} as the geometric average relative volatility yields:

$$\alpha_{i-ref} = \left[(\alpha_{i-ref})_1 (\alpha_{i-ref})_2 (\alpha_{i-ref})_3 \dots (\alpha_{i-ref})_{N-1} (\alpha_{i-ref})_N (\alpha_{i-ref})_{bot} \right]^{1/N_{min}}$$

- ◆ Equation above becomes

$$\left(\frac{x_i}{x_{ref}}\right)_{dist} = (\alpha_{i-ref})^{N_{min}} \left(\frac{x_i}{x_{ref}}\right)_{bot}$$

- ◆ Solving Eq. above for N_{min}

$$N_{min} = \frac{\ln \left[\left(\frac{x_i}{x_{ref}}\right)_{dist} / \left(\frac{x_i}{x_{ref}}\right)_{bot} \right]}{\ln(\alpha_{i-ref})}$$

- ◆ Eq. can be rewritten in terms of the fractional recoveries as

$$N_{min} = \frac{\ln \left[\frac{(Dx_i/Dx_{ref})_{dist}}{(Bx_i/Bx_{ref})_{bot}} \right]}{\ln(\alpha_{i-ref})}$$

Fenske (Winn) Equation – Derivation

- ◆ Equations may be rewritten in terms of fractional recovery: the Fenske equation for N_{\min} is obtained

$$N_{\min} = \frac{\ln\left[\frac{(D_{X_A}/D_{X_B})_{\text{dist}}}{(B_{X_A}/B_{X_B})_R}\right]}{\ln\alpha_{AB}}$$

- ◆ The fractional recoveries for component i are determined from:

$$(D_{X_A})_{\text{dist}} = (FR_A)_{\text{dist}} FZ_A \qquad (B_{X_A})_R = [1 - (FR_A)_{\text{dist}}] FZ_A$$

Fenske (Winn) Equation – Derivation

- ◆ Substituting one gets the Fenske equation for multicomponent systems, $(FR_A)_{\text{dist}}$ is the fractional recovery of A in the distillate, while $(FR_B)_{\text{bot}}$ is the fractional recovery of B in the bottoms.

$$N_{\min} = \frac{\ln \left[\frac{(FR_A)_{\text{dist}} (FR_B)_{\text{bot}}}{[1 - (FR_A)_{\text{dist}}][1 - (FR_B)_{\text{bot}}]} \right]}{\ln \alpha_{AB}}$$

- ◆ Calculation with the Fenske equation is straightforward if fractional recoveries of the two keys, A and B, are specified.
 - Equation can be used directly to find N_{\min} .
- ◆ The relative volatility can be approximated by a geometric average.
 - Once N_{\min} is known, the fractional recoveries of the non-keys (NK) can be found by writing Eq. for an NK component, C, and either key component.

Fenske Equation Methodology

- ◆ The use the Fenske equation to determine N_{\min} depends upon what is defined in the problem.
 - If two fractional recoveries are specified, one can solve Fenske equation and all of the ancillary equations directly.
 - If one is given two compositions, x_i and x_j , then one needs to make some assumptions...

Underwood Equations – (L/D)_{min}

- ◆ The other limiting condition for multi-component systems is the solution for the minimum reflux ratio, $(L/D)_{\min}$, which gives us an infinite number of stages.
- ◆ This method is known as the Underwood method or the Underwood equations.
 - First Underwood equation

$$\Delta V_{\text{feed}} = V_{\min} - \bar{V}_{\min} = \sum_{i=1}^c \frac{\alpha_{i-\text{ref}} F z_i}{\alpha_{i-\text{ref}} - \phi}$$

- Where ΔV_{feed} is the change in vapor flow rate at the feed stage. If q is known then $\Delta V_{\text{feed}} = F(1-q)$
- Second Underwood equation

$$V_{\min} = \sum_{i=1}^c \frac{\alpha_{i-\text{ref}} (D x_{i,\text{dist}})}{\alpha_{i-\text{ref}} - \phi}$$

- Once V_{\min} is known, L_{\min} is calculated from the mass balance

Underwood Equations – Cases

- ◆ There are 3 cases that we need to consider when using the Underwood equations:
- ◆ **Case A:** Non-keys do not distribute.
- ◆ **Case B:** Use the results from the Fenske equation and assume that the distributions of non-keys determined at total reflux are also valid at minimum reflux.
- ◆ **Case C:** Exact solution without further assumptions.

Underwood Equations – Case A Methodology

◆ Case A: Assume all NK's do not distribute: there are no intermediate NK's.

1. Specify the LK, HK, LNK's and HNK's.
2. Determine q for the feed conditions.
3. Determine all α_{i-ref} 's where the reference component is the HK.
4. Determine ΔV_F from Eq.:

$$\Delta V_F = F(1 - q)$$

5. Solve following Eq. for a single root, ϕ :

$$\Delta V_F = \sum_{i=1}^C \frac{\alpha_{i-ref}^{Fz_{F,i}}}{\alpha_{i-ref}^{-\phi}}$$

- Note that

$$\alpha_{LK-ref} < \phi < \alpha_{HK-ref}$$

- and choose the guess value between α_{LK} and α_{HK} .
- If one chose the HK as the reference for the relative volatilities, $\alpha_{HK-ref} = 1$.

Underwood Equations – Case A Methodology (continued)

6. Determine the NK rates from the assumption that the NK's do not distribute:

$$(Dx_{HNK\ i})_{dist} = 0 \quad (Dx_{LNK\ i})_{dist} = Fz_{F, LNK\ i}$$

7. Determine the LK and HK rates from Eqs:

$$(Dx_{LK})_{dist} = (FR_{LK})_{dist} Fz_{F, LK}$$

$$(Dx_{HK})_{dist} = [1 - (FR_{HK})_{bot}] Fz_{F, HK}$$

8. Determine V_{min} from Eq.:

$$V_{min} = \sum_{i=1}^C \frac{\alpha_{i-ref} (Dx_i)_{dist}}{\alpha_{i-ref} - \phi}$$

9. Determine D from Eq.:

$$D = \sum_{i=1}^C (Dx_i)_{dist}$$

Underwood Equations – Case A Methodology (continued)

10. Determine L_{\min} from Eq.:

$$L_{\min} = V_{\min} - D$$

11. Determine $(L/V)_{\min}$ using:

$$(L/V)_{\min} = L_{\min} / V_{\min}$$

12. Determine $(L/D)_{\min}$ from Eq.:

$$(L/D)_{\min} = \frac{(L/V)_{\min}}{1 - (L/V)_{\min}}$$

◆ Done

Underwood Equations – Case B Methodology

◆ Case B: Assume that the distribution of NKs determined from Fenske eq. at total reflux are also valid at minimum reflux.

1. Specify the LK, HK, NK's, LNK's and HNK's.
2. Determine q for the feed conditions.
3. Determine all α_{i-ref} 's where the reference component is the HK.
4. Determine ΔV_F from Eq.:
$$\Delta V_F = F(1 - q)$$

5. Solve following Eq. for a single root, ϕ :

$$\Delta V_F = \sum_{i=1}^C \frac{\alpha_{i-ref}^{Fz_{F,i}}}{\alpha_{i-ref} - \phi}$$

■ Note that

$$\alpha_{LK-ref} < \phi < \alpha_{HK-ref}$$

- and choose the guess value between α_{LK} and α_{HK} .
- If one chose the HK as the reference for the relative volatilities, $\alpha_{HK-ref} = 1$.

Underwood Equations – Case B Methodology (continued)

6. Determine the NK rates from the assumption that the distribution of NKs determined from Fenske eq. at total reflux are also valid at minimum reflux.

$$(Dx_{NK\ i})_{dist} = (Dx_{NK\ i})_{dist, Nmin}$$

7. Determine the LK and HK rates from Eqs:

$$(Dx_{LK})_{dist} = (FR_{LK})_{dist}^{FzF, LK}$$

$$(Dx_{HK})_{dist} = [1 - (FR_{HK})_{bot}]^{FzF, HK}$$

8. Determine V_{min} from Eq.:

$$V_{min} = \sum_{i=1}^C \frac{\alpha_{i-ref} (Dx_i)_{dist}}{\alpha_{i-ref} - \phi}$$

9. Determine D from Eq.:

$$D = \sum_{i=1}^C (Dx_i)_{dist}$$

Underwood Equations – Case B Methodology (continued)

10. Determine L_{\min} from Eq.:

$$L_{\min} = V_{\min} - D$$

11. Determine $(L/V)_{\min}$ using:

$$(L/V)_{\min} = L_{\min} / V_{\min}$$

12. Determine $(L/D)_{\min}$ from Eq.:

$$(L/D)_{\min} = \frac{(L/V)_{\min}}{1 - (L/V)_{\min}}$$

◆ Done

Underwood Equations – Case C Methodology

◆ Case C: Exact solution without further assumptions.

1. Specify the LK, HK, NK's, LNK's and HNK's.
2. Determine q for the feed conditions.
3. Determine all α_{i-ref} 's where the reference component is the HK.
4. Determine ΔV_F from Eq.:

$$\Delta V_F = F(1 - q)$$

5. Solve following Eq. for a single root, ϕ :

$$\Delta V_F = \sum_{i=1}^C \frac{\alpha_{i-ref}^{Fz} F_{,i}}{\alpha_{i-ref}^{-\phi}}$$

- Note that as an example, a C=5 system could be specified as:

$$\alpha_{LNK\ 1-ref} < \phi_1 < \alpha_{LNK\ 2-ref} < \phi_2 < \alpha_{LK-ref} < \phi_3 < \alpha_{HK-ref} < \phi_4 < \alpha_{HNK\ 1-ref}$$

- Choose a guess value for each ϕ between the α 's. If one chose the HK as the reference for the relative volatilities, $\alpha_{LHK-ref} = 1$.

Underwood Equations – Case C Methodology (continued)

6. Determine the LK and HK rates from Eqs:

$$(Dx_{LK})_{dist} = (FR_{LK})_{dist} F_{zF, LK}$$

$$(Dx_{HK})_{dist} = \left[1 - (FR_{HK})_{bot} \right] F_{zF, HK}$$

7. Determine V_{min} from Eq.:

$$V_{min} = \sum_{i=1}^C \frac{\alpha_{i-ref} (Dx_i)_{dist}}{\alpha_{i-ref} - \phi}$$

8. Determine D from Eq.:

$$D = \sum_{i=1}^C (Dx_i)_{dist}$$

Underwood Equations – Case C Methodology (continued)

9. Determine L_{min} from Eq.:

$$L_{min} = V_{min} - D$$

10. Determine $(L/V)_{min}$ using:

$$(L/V)_{min} = L_{min} / V_{min}$$

11. Determine $(L/D)_{min}$ from Eq.:

$$(L/D)_{min} = \frac{(L/V)_{min}}{1 - (L/V)_{min}}$$

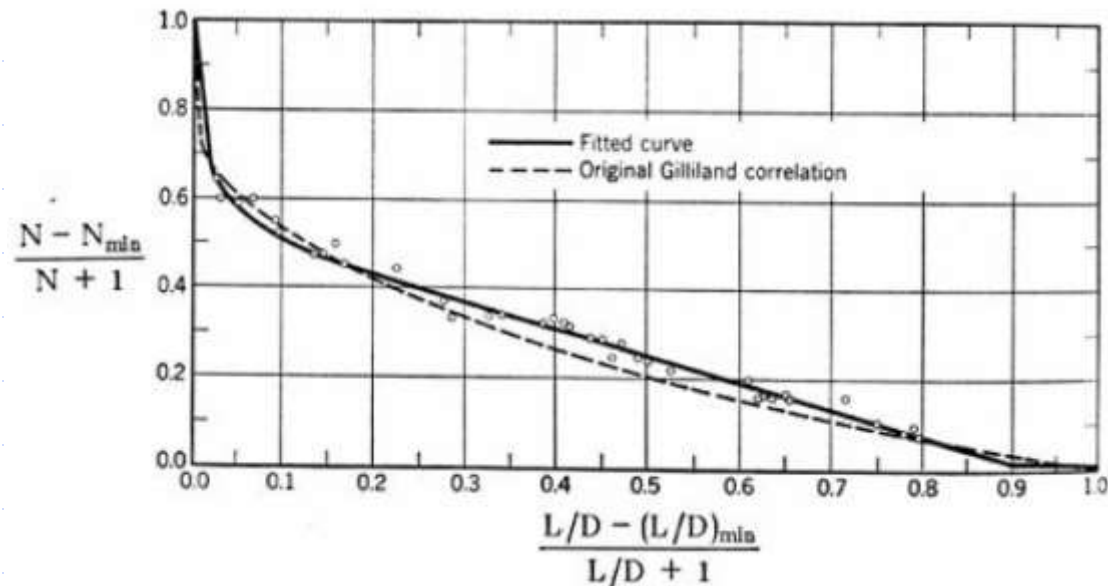

◆ Done

Gilliland Correlation – N and N_F

- ◆ Empirical relationship which relates the number of stages, N , at finite reflux ratio, $(L/D)_{\text{actual}}$ to the N_{min} and $(L/D)_{\text{min}}$.
 - N_{min} is determined from the Fenske equation.
 - $(L/D)_{\text{min}}$ is determined from the Underwood equations.
- ◆ Gilliland correlation as modified by Liddle:

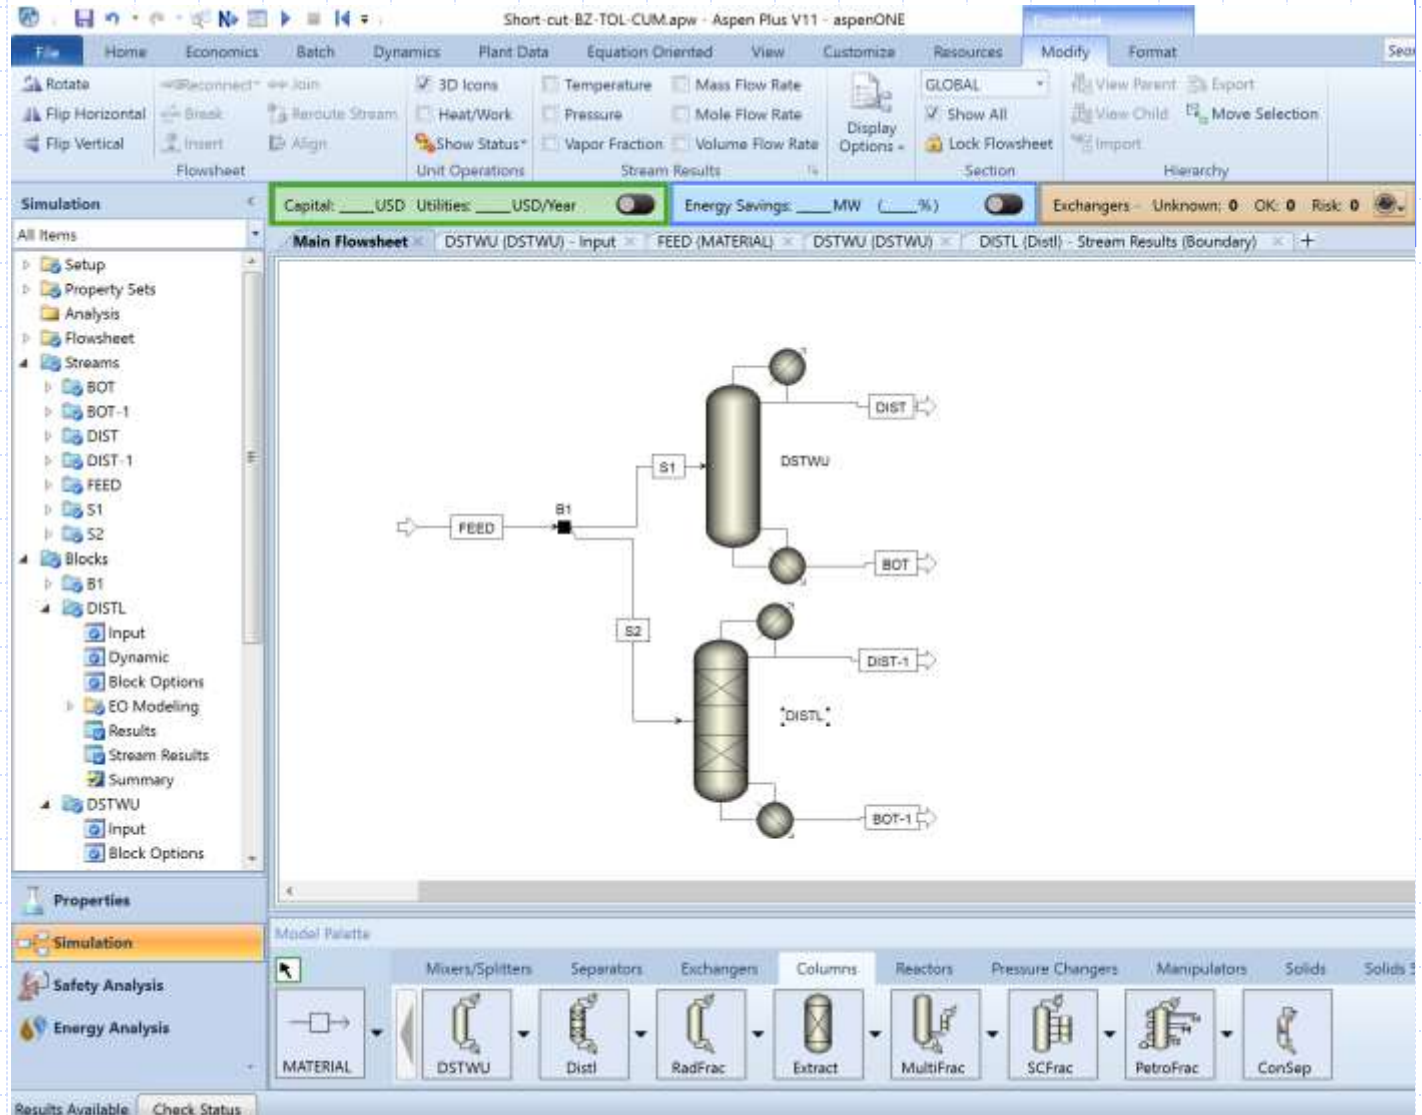

Validly limits of the diagram:

- N. components $2 < NC < 11$
- Column Pressure : $0 < P < 40$ bar
- Relative volatility: $1.11 < \alpha_{ik} < 4.05$
- Reflux ratio min: $0.53 < r_{\text{min}} < 9.09$
- Minimum n. stages: $3.4 < N_{\text{min}} < 60.3$
- Thermal conditions: $-0.42 < \varphi_F < 0.72$.

Aspen+ short cut methods

- ◆ DSTWU
- ◆ DISTL

Using Shortcut method: DSTWU

◆ DSTWU:

- DSTWU performs shortcut design calculations for single-feed, two-product distillation columns with a partial or total condenser.
- It assumes constant molal overflow and constant relative volatilities.
 - ◆ It is based on equations of:
 - ◆ Winn for Minimum number of stages
 - ◆ Underwood for Minimum reflux ratio
 - ◆ Gilliland for calculation of reflux ratio for a specified number of stages or the required number of stages for a specified reflux ratio
- For the specified recovery of light and heavy key components, DSTWU estimates:
 - ◆ Minimum reflux ratio
 - ◆ Minimum number of theoretical stages
- DSTWU then estimates one of the following:
 - ◆ Required reflux ratio for the specified number of theoretical stages
 - ◆ Required number of theoretical stages for the specified reflux ratio
- DSTWU also estimates the optimum feed stage location and the condenser and reboiler duties.

Using Shortcut method: DISTL & ConSep

◆ DISTL:

- Distl simulates multistage multicomponent columns with a feed stream and two product streams.
- Distl performs shortcut distillation rating calculations using Edmister approach: assumes constant mole overflow and constant relative volatilities.

◆ ConSep:

- Use ConSep to develop design parameters and perform feasibility studies for distillation columns.
- It requires the definition of the splitting of three key components and the mapping of the others relative to key components

Example: benzene, toluene, cumene separation with short-cut methods

◆ Components
