- Orbite varie

# Leggi di Keplero

L'orbita di un pianeta è un'ellisse con il Sole in uno dei fuochi

Una linea congiungente il Sole ad un pianeta spazza aree uguali in intervalli di tempo uguali

**2nd Law**

**3rd Law**

Il quadrato del periodo dell'orbita di un pianeta è proporzionale al cubo della sua distanza media dal Sole

# Leggi di Newton 1/2

- 1<sup>a</sup> Legge: La legge di inerzia
- 2<sup>a</sup> Legge: Forza = massa × accelerazione
- 3<sup>a</sup> Legge: Azione e reazione

Quando una forza è applicata a un corpo, questo si sposta e la sua velocità cambia. L'accelerazione è la variazione della velocità nel tempo. La forza è proporzionale alla massa del corpo e all'accelerazione. La forza di gravitazione universale è la forza che attrae tutti i corpi. La forza di gravitazione universale è proporzionale al prodotto delle masse dei due corpi e inversamente proporzionale al quadrato della distanza tra di loro.

LA LEGGE DI GRAVITA':  $F = \frac{GMm}{r^2}$

|   |                                                                                               |
|---|-----------------------------------------------------------------------------------------------|
| F | Forza gravitazionale tra due corpi                                                            |
| G | Costante di gravitazione universale: $G = 6.670 \times 10^{-11} \text{ N.m}^2.\text{kg}^{-2}$ |
| M | Massa di un corpo (Terra o Sole)                                                              |
| m | Massa di un altro corpo (il satellite)                                                        |
| r | Separazione tra i corpi                                                                       |

$$GM_{\text{Earth}} = \mu = 3.986004418 \times 10^{14} \text{ m}^3.\text{s}^{-2}$$

$$f = -4.5 \cdot 10^{-6} (1+r) A/m \text{ m/s}^2$$

$r$  = coefficiente riflessione

# ORBITE

# Low Earth Orbit (LEO)

✦ LEOs are either circular (or elliptical) orbits less than 2 000 km above the surface of the earth

- Satellites generally some 700 to 1400 km up
- Orbit periods between 90 to 120 minutes
  - Maximum time during which a satellite is above the horizon for an observer on the earth is 20 minutes.
- Footprint radius is generally 3 000 to 4 000 km
- A global system requires many satellites
  - Needs to hand over the service to other satellites
- Need to be able to cope with large orbital drifts

# Medium Earth Orbits (MEO)

---

- ✦ MEOs are circular orbits at an altitude of around 10000 km, with an orbit period of around 6 hours
  - The time during which a MEO satellite is in view for an observer on the earth is in the order of a few hours
  - A global communications system using this type of orbit, requires a modest number of satellites (around 10 to 20) in 2 to 3 orbital planes to achieve global coverage
  - Compared to a LEO system, hand-over is less frequent, and propagation delay and free space loss are greater

# Geosynchronous Orbit (GEO)

---

- ✦ A circular orbit with an orbital period equal to that of the Earth
  - When in the equatorial plane (geostationary: inclination =  $0^\circ$ ), it appears fixed from an observer on Earth
    - This is achieved with an orbital height of 35 786 km (or an orbital radius of 6.6107 Equatorial Earth Radii)
  - A GEO orbit has small non-zero values for inclination and eccentricity
    - causing the satellite to trace out a small figure of eight in the sky
  - The round-trip delay is approximately 250 ms

| $TL_3$     | = | 386322 km    |
| $TL_{4,5}$ | = | 384400 km    |
| $TS_2$     | = | $1.5E+06$ km |
| $TS$       | = | $1.5E+08$ km |

# Lagrangian points

defined by and between the 2 large masses  $M1$  and  $M2$ . It is understood of the Lagrangian points where the gravitational forces effectively cancel each other out. They are defined by the 2 large masses, where the gravitational forces of the 2 large masses balance each other out.

- ✦ L3: lies on the line defined by the 2 large masses, the combined pull of Earth and Sun again causes it to have the same period as the Earth

For the 2 equilateral triangles in the plane of orbit, (L4) the smaller mass wrt its orbit around the larger mass. If the 2 masses are equal  $\Rightarrow$  gravitational forces from the 2 masses are equal  $\Rightarrow$  the resultant force is exactly that required to maintain equilibrium with the rest of the system: being both the centre of mass and the barycenter of the system, the resultant force is exactly that required to maintain equilibrium with the rest of the system.

# Trasferimento LEO-GEO: GTO 3/3

| LEO    |            | GEO    |            | ELLISSE          |             |
|--------|------------|--------|------------|------------------|-------------|
| h      | 400 km     | h      | 35781 km   | a                | 24469 km    |
| radius | 6778 km    | radius | 42160 km   | $r_A$            | 6778 km     |
| v      | 7.669 km/s | v      | 3.075 km/s | $r_B$            | 42160 km    |
| i      | 28 deg     | i      | 0 deg      | $v'_A$           | 10.066 km/s |
|        | 0.4887 rad |        | 0 rad      | $v'_B$           | 1.618 km/s  |
|        |            |        |            | $\tau$           | 19046 s     |
|        |            |        |            |                  | 317.4 min   |
|        |            |        |            | $\Delta v_A$     | 2.397 km/s  |
|        |            |        |            | $\Delta v_B$     | 1.456 km/s  |
|        |            |        |            | $\Delta v_{TOT}$ | 3.854 km/s  |

Tutto trasferimento  
effettuato in A

|                      |            |
|----------------------|------------|
| $\Delta v_{plane}$   | 3.710 km/s |
| $\Delta v_{TOT}$     | 7.564 km/s |
| $\Delta v_{plane,A}$ | 4.880 km/s |
| $\Delta v_{TOT}$     | 6.337 km/s |

# Aggiustamenti di orbita

Attrito Atmosferico

LEO

$$\Delta v_{\text{rev}} = \pi (C_D A / m) \rho a v$$

GEO,  $i=0^\circ$

Triassialità della Terra

$$\Delta v_{\text{anno}} = 1.715 \sin(2|\text{long} - \text{long}_s|) \text{ m/s} \quad (\text{long}_s = 75^\circ/225^\circ \text{ E})$$

Forze Gravitazionali del Sole e della Luna

$$\Delta v_{\text{Luna, anno}} = 102.67 \cos \alpha \sin \alpha \text{ m/s /anno} \quad \sim 36.93 \text{ m/s /anno}$$

$$\Delta v_{\text{Sole, anno}} = 40.17 \cos \gamma \sin \gamma \text{ m/s /anno} \quad \sim 14.45 \text{ m/s /anno}$$

# Appuntamenti in orbita

$$AP: \tau_{AP} = \pi \sqrt{a^3/\mu} = \tau_{BP} = \tau_H$$

$$BP: \tau_{BP} = \alpha_L/\omega_B = \alpha_L \sqrt{r_B^3/\mu}$$

$$\alpha_L = \pi - \Phi_f$$

$$t_w \omega_A - t_w \omega_B = \Phi_i - \Phi_f \quad (+2k\pi)$$

$$(\Phi_i = 0)$$

$$t_w = (\alpha_L - \pi + 2k\pi) / (\omega_A - \omega_B)$$

$$= (\tau_H \omega_B - \pi + 2k\pi) / (\omega_A - \omega_B)$$

$$t_{\text{tot}} = t_w + \tau_H + t_o$$

# Parametri Ellisse

$$v_t = v \cos \gamma (*)$$

$$v_r = v \sin \gamma$$

$\gamma=0$  per orbite  
circolari ( $v=v_t$ ,  $v_r=0$ )
