Mesosopic simulations details

in collaboration with Sabrina Priol Paola Posocco and Maurizio Fermeglia

- ✓ *Self-assembled organization was predicted at the nanoscale using coarse grained (CG) simulations in presence of solvent*
- ✓ *CG calculations allow to reach time and length scales larger than classical atomistic predictions and closer to those involved in the experimental phenomena*
- ✓ *An ad hoc multiscale molecular modeling procedure was developed. It employs the information obtained from atomistic molecular dynamics simulation to parametrize mesoscale dissipative particle dynamics (DPD) models, thus incorporating all chemical details even at the CG level*

gold nanorods

Seed-mediated Growth in Solution

1. Chemical reduction of a metal salt with strong reducing agent (NaBH_4),
2. Use of a capping agent to prevent particle growth (citrate),
3. Addition of the seeds to a solution that contains more metal salt, a weak reducing agent (AA) and a rodlike micellar template (cetyltrimethylammonium bromide, CTAB).

Aspect ratio is controlled by the ratio of metal seed to metal salt.

gold nanorods

Figure 2. Seed-mediated growth approach to making gold and silver nanorods of controlled aspect ratio. The specific conditions shown here, for 20 mL volume of seed solution, lead to high-aspect ratio gold nanorods. (bottom right) Transmission electron micrograph of gold nanorods that are an average of 500 nm long.

Sau and Murphy, Langmuir **2004**, 20, 6414.

gold nanorods

Influence of the reaction parameters

- ✓ Effect of the Seed Concentration

An **increase** in the $[\text{Au}]_{\text{seed}}$ **decreased** the **rod length** for a given concentration of Au^{3+} .

- ✓ Effect of AA concentration

The **rod length decreases** with an **increase in [AA]** keeping all other conditions the same.

- ✓ Effect of AgNO_3

When **silver nitrate is not used** nanorods are obtained in **low yield** and quite **long**.

- ✓ Effect of $[\text{Au}^{3+}]$

The **less** quantity of **Au^{3+} ions** per seed particle available the **short** are the nanorods.

- ✓ Effect of [CTAB]

Lower CTAB concentrations can lead to **non-rod-shaped** particles.

gold nanorods

Variation in the absorption of visible light

Short aspect ratio Au nanorods are especially interesting because of their optical properties: they exhibit transverse and longitudinal plasmon bands.

Aspect ratio: the length of the major axis divided by the width of the minor axis.
The larger the aspect ratio, the more red-shifted the longitudinal plasmon band.

gold nanorods

Figure 7. Cartoon illustrating “zipping”: the formation of the bilayer of CnTAB (squiggles) on the nanorod (black rectangle) surface may assist nanorod formation as more gold ion (black dots) is introduced. Reproduced from ref 104 with permission.

gold nanorods

STEP 1: SYMMETRY BREAKING IN FCC METALS

STEP 2: PREFERENTIAL SURFACTANT BINDING TO SPECIFIC CRYSTAL FACES

Figure 8. Proposed mechanism of surfactant-directed metal nanorod growth. The single crystalline seed particles have facets that are differentially blocked by surfactant (or an initial halide layer that then electrostatically attracts the cationic surfactant). Subsequent addition of metal ions and weak reducing agent lead to metallic growth at the exposed particle faces. In this example, the pentatetrahedral twin formation leads to Au {111} faces that are on the ends of the nanorods, leaving less stable faces of gold as the side faces, which are bound by the surfactant bilayer.

gold nanorods - functionalization

Figure 9. Cartoon of biotin-streptavidin assembly of gold nanorods; a biotin disulfide is added to biotinylate the rods, and subsequent addition of streptavidin causes noncovalent assembly. Inset: transmission electron micrograph of gold nanorod-streptavidin assemblies. The original data are from ref 86.

Nanoparticle-based Sensors

Figure 7. Forming DNA-mediated dimers of Au nanoparticles requires each nanoparticle to be functionalized with one oligonucleotide, with both oligonucleotides being complementary to each other. a) When phosphine- (or citric acid) stabilized Au nanoparticles and thiol-modified oligonucleotides react, DNA binds with its thiol group to the Au surface. However, even for 1:1 mixtures of DNA and Au, Au nanoparticles with more or less than one bound oligonucleotide will result; b) Au nanoparticles with a different number of DNA molecules bound per particle can be sorted by gel electrophoresis (image adapted from ref. [87]). Individual bands of nanoparticles with a discrete number of DNA molecules per particle can be observed and extracted from the gel; c) Au nanoparticles with one DNA molecule can be mixed with another solution of Au nanoparticles modified with a complementary DNA sequence. The single-stranded DNA molecules hybridize to a double strand, thus connecting the Au nanoparticles. The resulting dimers can be observed by TEM imaging (the Au-nanoparticle dimers shown comprise two 10-nm-diameter Au nanocrystals; the DNA molecules cannot be seen by TEM). Image courtesy of D. Zanchet et al.^[7]

Hybrid Nanoparticle–Liposome Detection of Phospholipase Activity

Daniel Aili[†], Morgan Mager[†], David Roche and Molly M. Stevens
Nano Letters 2010

A flexible nanoparticle-based **phospholipase** (PL) assay is demonstrated in which the enzymatic substrate is decoupled from the nanoparticle surface. Liposomes are loaded with a polypeptide that is designed to heteroassociate with a second polypeptide immobilized on gold nanoparticles. Release of this polypeptide from the liposomes, triggered by PL, induces a folding-dependent nanoparticle bridging aggregation. The colorimetric response from this aggregation enables straightforward and continuous detection of PL in the picomolar range. The speed, specificity, and flexibility of this assay make it appropriate for a range of applications, from point of care diagnostics to high-throughput pharmaceutical screening.

A nanoplasmonic molecular ruler for measuring nuclease activity and DNA footprinting

nature nanotechnology **2006**, 1, 47

Figure 1. Design of the Au–DNA nanoplasmonic molecular ruler. a, Synthesis process of the Au–DNA nanoconjugate. The 20-nm Au nanoparticle modified with a phosphine surfactant monolayer was enclosed by a layer of synthesized 54-bp dsDNA. A thiol group and the FITC (fluorescein isothiocyanate) fluorophore (as indicated by green star) were synthesized at each end of the dsDNA, respectively. Through the thiol–Au chemistry, the dsDNA was tethered onto the Au nanoparticles. b, The dsDNA contains endonuclease incision sites positioned at 12, 24, 36 and 48 bp from the Au-nanoparticle-tethered end. The fluorescent labelling (FITC) is only for further confirmation of the nuclease reactions, and is not necessary for plasmon resonance measurements.

catalytic activity of MPC-C12-TEG-C12-P2-H

Log of the apparent second order rate constant against pH for the hydrolysis of DNPB catalyzed by nanoparticles Au-PEP (●) nanoparticles Au-2 (○), and S-acetylated peptide 1 (◆). The solid lines represent the best fits of functions describing the dissociation of residues involved in catalysis with pKa values of 4.2, 7.2 and 9.9, in the case of Au-PEP, 4.2 and 8.1 for Au-2, and 6.1 and 9.2 for S-acetylated 1. The dotted lines represent the calculated contribution of each species to the solid curve for Au-PEP. Conditions: [catalyst]= 4.0×10^{-5} M, [buffer]=10-20 mM, 25°C.

3000-fold rate acceleration (over Ac-C12-HFOH)
500-fold acceleration (over AcS-C12-P2-H)

catalytic activity of MPC-C8-TEG-C12-P2-H

Figure 2. Dependence of the initial rate (M s^{-1}) of intermediate formation (\circ) and its hydrolysis (\bullet) with Z-Leu-PNP and that of hydrolysis (\blacksquare) with Z-Gly-PNP upon substrate concentration. Conditions: $[\text{S-C12-P2-OH}] = 1.3 \times 10^{-5} \text{ M}$ (bound to Au-PEP), pH 7, 25°C.

Detection and identification of proteins using nanoparticle–fluorescent polymer ‘chemical nose’ sensors

C.-C. YOU, O. R. MIRANDA, B. GIDER¹, P. S. GHOSH, I.-B. KIM, B. ERDOGAN¹, S. A. KROVI, U. H. F. BUNZ, VINCENT M. ROTELLO
nature nanotechnology VOL 2 | MAY 2007 , page 318

Figure 1 Fluorophore displacement protein sensor array. **a**, Displacement of quenched fluorescent polymer (dark green strips, fluorescence off; light green strips, fluorescence on) by protein analyte (in blue) with concomitant restoration of fluorescence. The particle monolayers feature a hydrophobic core for stability, an oligo(ethylene glycol) layer for biocompatibility, and surface charged residues for interaction with proteins. **b**, Fluorescence pattern generation through differential release of fluorescent polymers from gold nanoparticles. The wells on the microplate contain different nanoparticle–polymer conjugates, and the addition of protein analytes produces a fingerprint for a given protein.

Figure 2 Structural features of nanoparticles, polymer transducer and target analytes. **a**, Chemical structure of cationic gold nanoparticles (NP1–NP6) and anionic fluorescent polymer PPE- CO_2 ($m \approx 12$, where m refers to the number of repeated units in the polymer). **b**, Surface structural feature and relative size of seven proteins and the nanoparticles used in the sensing study. Colour scheme for the proteins: nonpolar residues (grey), basic residues (blue), acidic residues (red) and polar residues (green).

Figure 4 Array-based sensing of protein analytes at 5 μM . **a**, Fluorescence response (ΔI) patterns of the NP-PPE sensor array (NP1–NP6) against various proteins (CC, cytochrome *c*; β -Gal, β -galactosidase; PhosA, acid phosphatase; PhosB, alkaline phosphatase; SubA, subtilisin A). Each value is an average of six parallel measurements. **b**, Canonical score plot for the first two factors of simplified fluorescence response patterns obtained with NP-PPE assembly arrays against 5 μM proteins. The canonical scores were calculated by LDA for the identification of seven proteins. The 95% confidence ellipses for the individual proteins are also shown.

LDA = linear discriminant analysis

photothermal therapy

travel as far through living tissue as a magnetic field can. "We wanted something that

Kimberly Hamad-Schifferli (right) hopes to control proteins by attaching tiny gold particles to them — in a radio field the particle heats up, altering the protein's structure and inactivating it.

'nano' word is over-used and over-hyped," says John Ryan, director of the Nanobiotech-

paced activities of daily life in the cell. And for those in the nanosystems alliance, nanotechnology is the best way to get a grip on the many fleeting processes involved. Alliance member Leroy Hood, a molecular biologist at the Institute for Systems Biology in Seattle, predicts that nanotechnology will reveal as much new information about the cell as did the automated DNA sequencer — a device that he invented. "The combination of microfluidics and nanotechnology," Hood asserts, "will transform how biologists do everything." ■
