

# Ingegneria genetica e medicina: paure e perplessità

# Che cos'è l'ingegneria genetica?

Consiste nell'utilizzo di tecniche sperimentali per produrre molecole di DNA che contengono nuovi geni o nuove combinazioni di geni

Le tecniche dell'ingegneria genetica coinvolgono spesso l'isolamento, la manipolazione e la reintroduzione del DNA all'interno di cellule eterologhe o, più nello specifico, di organismi modello

# Che cos'è l'ingegneria genetica?

Consiste nell'utilizzo di tecniche sperimentali per produrre molecole di DNA che contengono nuovi geni o nuove combinazioni di geni

## Perchè?

- Per la ricerca pura molto utili per comprendere a fondo la funzione di una determinata proteina
- Per la ricerca applicata, il fine ultimo è quello di conferire a determinati organismi caratteristiche importanti per svolgere determinati scopi.

Biomedico: produzione di farmaci ricombinanti

Agricolo: cereali resistenti agli erbicidi

# L'ingegneria genetica applicata all'uomo: la terapia genica

# TERAPIA GENICA

- Introduzione di un transgene in una cellula allo scopo di correggere un errore innato del metabolismo o per fornire una nuova funzione cellulare o per neutralizzare un prodotto espresso dalla cellula

# Terapia genica somatica: quali i migliori candidati?

- Malattie monogeniche, con ereditarietà recessiva o legata all'X
- Morbidità o mortalità significative: tumori e malattie cardiovascolari
- Terapia attuale inadeguata o non disponibile
- La sede cellulare del difetto genetico deve essere facilmente accessibile

# Malattie Monogeniche candidate alla Terapia Genica

| Disease                                                                                      | Defect                                                      | Incidence                      | Target Cells                                    |

# Malattie ad alta mortalità candidate alla Terapia Genica

## Some Acquired Diseases that are Candidates for Gene Therapy

| Disease               | Defect                                           | Incidence                                                           | Target Cells                                                            |
|-----------------------|--------------------------------------------------|---------------------------------------------------------------------|-------------------------------------------------------------------------|
| Cancer                | Many causes, including genetic and environmental | 1 million/year in USA                                               | Variety of cancer cell types, in liver, brain, pancreas, breast, kidney |
| Neurological diseases | Parkinson's, Alzheimer's, spinal-cord injury     | 1 million Parkinson's and 4 million Alzheimer's patients in the USA | Neurons, glial cells, Schwann cells                                     |
| Cardiovascular        | Restenosis, arteriosclerosis                     | 13 million in USA                                                   | Arteries, vascular endothelia walls                                     |
| Infectious diseases   | AIDS, hepatitis B                                | Increasing numbers                                                  | T cells, liver, macrophages                                             |
| Rheumatoid arthritis  | Autoimmune inflammation of joints                | Increasing numbers with aging population                            |                                                                         |

# Chi investe in terapia genica?

Geographical Distribution of Gene Therapy Clinical Trials  
(by Country)

- USA 65% (n=815)
- UK 12% (n=150)
- Germany 5.9% (n=74)
- Switzerland 3.3% (n=42)
- France 1.6% (n=20)
- Belgium 1.5% (n=19)
- Australia 1.3% (n=17)
- Canada 1.3% (n=17)
- Japan 1.3% (n=16)
- Italy 1.2% (n=15) ←
- Others 5.9% (n=75)

# Sviluppo di una nuova terapia

Ricerca pre-clinica

Sperimentazione clinica  
(trial clinico)

**Clinical Trials**  
*Phases I - III*

**Results**

# ***Trials*** clinici in terapia genica

La sperimentazione clinica (clinical trial) e' caratterizzata da diverse fasi:

- Fase I: si risponde al quesito: *quanto farmaco può essere somministrato senza causare effetti avversi gravi?*
- Fase II: si valuta il meccanismo di azione del farmaco, e si continua la valutazione sulla sicurezza di fase I, su un gruppo più ampio di volontari e pazienti
- Fase III: Quando un farmaco è considerato **efficace** e **sicuro**, viene somministrato a un numero alto di pazienti
- Fase IV: Detta anche sorveglianza Post-Marketing, mira a trovare ogni evento avverso raro o a lungo tempo, su una più grande popolazione di pazienti

Phases of Gene Therapy Clinical Trials

# Terapia genica: Come?

## *ex vivo*

Le cellule bersaglio sono prelevate dal paziente, modificate geneticamente in laboratorio e reintrodotte nello stesso individuo

- ✓ no problemi immunologici
- ✓ efficienza delle metodiche di trasduzione in vitro
- ✓ solo alcune malattie (immunologiche,ematologiche, metaboliche)

## *in vivo*

il transgene viene somministrato per via sistemica

- ✓ cellule e tessuti poco accessibili;
- ✓ scarsa efficienza di trasduzione, barriere fisiche

## *in situ*

il transgene viene rilasciato localmente nel sito di azione (mediante iniezione i.m. o intratumorale o per inalazione ecc...)

- ✓ tumori localizzati; patol. dell'apparato respiratorio; tessuto cutaneo ecc...

# In vivo gene therapy

# Ex vivo gene therapy

# *Strategie di terapia genica*

- ✓ Compensazione genica
- ✓ Riparo genico
- ✓ Inattivazione
- ✓ Suicida
- ✓ Anti-angiogenica
- ✓ Anticorpale
- ✓ Anti-infiammatoria
- ✓ Vaccinazione
- ✓ Terapie cellulari

**Come raggiungere il nucleo della cellula?**

# Tecniche di trasferimento genico

## Lipofezione

Liposomi

Lipidi cationici

Complessi liposomi/proteine

SNALPS

## Vettori virali

Retroviruses

Lentiviruses

Adenoviruses

Virus adeno-associati (AAV)

## Metodi fisici

Microiniezione

Elettroporazione

Gene Gun

DNA complessato a nanoparticelle

Recombinant  
DNA molecule

DNA nudo

# DNA nudo e metodi fisici

## Vantaggi

- assenza di immunogenicità
- alta efficienza ex-vivo
- rilascio di grossi geni
- utile per le vaccinazioni a DNA

## Svantaggi

- espressione transitoria
- in vivo solo per tessuti superficiali (cute), muscolo, cuore, fegato

# *Vettore Virale ideale*

- ✓ di facile produzione e in elevate quantità
- ✓ esprimibile per un lungo periodo e regolabile
- ✓ sicuro, cioè inerte dal punto di vista immunologico
- ✓ selettivo per determinati tipi cellulari
- ✓ capace di trasportare geni piccoli e grandi
- ✓ capace di integrarsi in siti specifici del genoma
- ✓ capace di infettare sia cellule in divisione che quiescenti

# Vettori virali

Adenovirus (~36 kb genome)

Adeno-associated virus (4.7 kb genome)

Retrovirus (7-10 kb genome)

Lentivirus (9-10 kb genome)

## Vantaggi

- ✓ altamente efficienti nel trasferimento genico
- ✓ espressione a lungo-termine

## Svantaggi

- ✓ reazione immunitaria
- ✓ tossicità
- ✓ integrazione random/ mutagenesi inserzionale\*

# Adeno-associated virus (AAV)

## Taxonomy

Family: Parvovirus

Subfamily: Parvoviridae

Genus: Dependovirus

Type: AAV 1-12

AAV

Ad

## Morphology

Particles are icosahedral, non-enveloped, 18-26 nm diameter, 50% protein (VP1-3) 50% DNA. Resistant to inactivation by solvents, pH and heat.

## Genome

Linear, non-segmented, ssDNA ~5 kb.

AAVs package equal amounts of (+) and (-) strands.

Xie et al. 2002

# Gene transfer using Adeno-Associated Virus (AAV) vectors

1. Based on a widely diffused, non pathogenic virus
2. Vectors retain less than 10% of the viral genome
3. Vectors do not express any viral protein (not inflammatory and not immunogenic); long term ensured in vivo
4. Expression of the therapeutic gene can be driven by any desirable promoter
5. High titer vector preparations are obtained by virion purification
6. Mixing of different rAAV preparations results in the simultaneous expression of gene combinations in vivo

Xie et al. 2002

Family: Parvovirus  
Genus: Dependovirus  
Type: AAV 1-9  
Size: 18-26 nm  
Genome: ssDNA ~5 kb

AAV efficiently transduces permissive tissues and promotes persistent transgene expression

Optimal AAV serotypes for in vivo gene transfer to various tissues

# La tessuto-specificita' di infezione e' data dalle proteine del capside

- **RECETTORE?**

# Peculiarities of the eye as a target for gene therapy

The eye is a site of immune-privilege

Most cells in the post-natal eye are terminally differentiated and prone to degenerative processes

Its compartmentalized anatomy (blood-retina barrier) enables local vector delivery in small volume with low likelihood of systemic dissemination

The eye is readily accessible for *in vivo* assessment by optical imaging and electrophysiological techniques

The results of the first clinical trials for ocular cancer and angiogenic disease have now been reported. One trial of gene replacement therapy for inherited retinal degeneration commenced recently and further such trials are expected to begin imminently

There are many animal models available

AAV is the only vector to efficiently transduce both RPE and photoreceptors

*AAV2 subretinal*

*AAV8 subretinal*

*AAV2 intravitreal*

# Amaurosi congenita di Leber

E' una delle forme più gravi di cecità congenita, presente alla nascita o nei primi mesi di vita.

Incidenza 3 casi ogni 100.000 nati vivi.

Malattia ereditaria a trasmissione autosomica recessiva. Sono stati individuati sei geni diversi, la cui mutazione porta al manifestarsi della malattia; si tratta di geni responsabili dello sviluppo, della funzionalità e del mantenimento della retina. Tuttavia questi geni rendono conto solo del 16% dei casi.

RPE65 codifica per retinolo cis/trans isomerasi dell' epitelio pigmentato

TERAPIA GENICA AAV-mediata

# Napoli, nuova terapia genica rende la vista a due bambini ciechi

La malattia è causata da mutazioni in un gene chiamato RP65 e la terapia fornisce una copia funzionante di questo gene

Due bambini, uno di 8 anni e uno di 9, **ciechi dalla nascita** per una particolare forma di **distrofia retinica ereditaria**, hanno recuperato la vista grazie a una tecnica innovativa eseguita **per la prima volta in Italia** nella Clinica oculistica dell'Università degli Studi della Campania "Luigi Vanvitelli". La malattia è causata da **mutazioni** in un gene chiamato **RP65** e la terapia, sviluppata da Novartis, fornisce una **copia funzionante** di questo gene.

I risultati ottenuti con la nuova metodologia, denominata "**Luxturna**", sono stati illustrati da **Francesca Simonelli**, direttrice della Clinica Oculistica dell'ateneo. La copia del gene RP65 è in grado, attraverso una **singola somministrazione**, di migliorare la capacità visiva dei pazienti.

La tecnica e i risultati sono stati presentati dalla Simonelli presso il Policlinico di Napoli. Tra i partecipanti: Giuseppe Paolisso, Rettore dell'Università degli Studi della Campania Luigi Vanvitelli; Giuseppe Limongelli, direttore del Centro di coordinamento Malattie Rare della Regione Campania; Fulvio Luccini, Patient Access Head Novartis.

# Challenges to gene therapy for DMD

Gene therapy requires delivery of a new gene to the vast majority of muscles in the body and to the heart - a daunting challenge, since muscle tissues makes up **>40% of body mass**

The **dystrophyn mRNA** is **14 kb** in size. A delivery vector must be identify that can carry this expression cassette; alternatively, truncated version of the gene can be used

Muscle transduction must not trigger toxic or immunological reactions that are harmful to the patient or that lead to further muscle damage

# Distrofina e DGC

R254 *Human Molecular Genetics, 2006, Vol. 15, Review Issue No. 2*

**Figure 1.** Schematic outline of full-length dystrophin, minidystrophin and microdystrophin and their interaction with other cellular proteins. Spectrin-like repeats are numbered from 1 to 24 (positively charged repeats are in red color, other repeats are in yellow color). Proline-rich hinges are numbered from 1 to 4. Hinge 3 is in pink color to indicate that it can be cleaved by viral protease. Hinge 2 to repeat 19 are deleted in minidystrophin. Repeat 4–23 and the C-terminal domain are deleted in microdystrophin. Not drawn to scale.

**minidistrofine (~6-7 kb) e microdistrofina (~4 kb)**

Queste versioni ridotte della distrofina presentano delezioni comuni della regione centrale a **bastoncello** e nel dominio C-terminale della proteina parentale, lasciando intatti i domini funzionali essenziali della proteina, in particolare quello ricco in cisteine (CR)

# Duchenne muscular dystrophy - natural animal models

mdx mice (point mutation leading  
to a premature truncation)

xdm golden retriever dog  
(exon 7 skipping)

# Vectors for muscle gene therapy

- **Ad “gutless”**: Ad vectors have relative large cloning capacity, can be grown at high titers and display relative efficient infection of muscle. However, traditional Ad vectors elicit a robust cellular immune response
- **AAV**: AAV vectors are of great interest as they efficiently infect muscle and persist for years. New serotypes available
- **Plasmid DNA**: displays a remarkable ability to transfer genes to muscle, specially if coupled with high pressure injection and/or electroporation

The first clinical trial, closed in 2006, entailed the injection of a plasmid containing the whole dystrophin cDNA under the control of the CMV promoter into the radialis muscle of 9 DMD/BMD patients. However, dystrophin expression resulted too low and not homogenous.

Different strategies can be used to increased transduction efficiency, including polymeres, ultrasounds (with microbubbles), and **electroporation**

LA VICENDA

## Sofia, la bambina di Napoli curata con il farmaco più costoso al mondo

Ha 6 mesi e una malattia rara: per la terapia spesi 1,9 milioni. Il papà: «Per noi era un tunnel senza fine, finalmente ora possiamo sperare di vedere la luce»

di **Fulvio Bufi**

Starting ZOLGENSMA

## ZOLGENSMA targets the genetic root cause of SMA

As a gene therapy, ZOLGENSMA® (onasemnogene abeparvovec-xioi) is designed to target the genetic root cause of spinal muscular atrophy (SMA) by replacing the function of the missing or nonworking *SMN1* gene with a new, working copy of a human *SMN* gene. ZOLGENSMA does not change or become a part of the child's DNA.

To help you understand how this is possible, let's look at how ZOLGENSMA works.

SCROLL  
▼

### What is ZOLGENSMA?

ZOLGENSMA is a prescription gene therapy used to treat children less than 2 years old with spinal muscular atrophy (SMA). ZOLGENSMA is given as a one-time infusion into a vein. ZOLGENSMA was not evaluated in patients with advanced SMA.

## ***SMN1* gene missing or nonworking**

### **A targeted approach**

ZOLGENSMA targets the genetic root cause of SMA by replacing the function of the missing or nonworking gene, called the *SMN1* gene. This gene is critical to making SMN protein.

functioning motor neuron cell

### **The importance of SMN protein**

SMN protein is essential to motor neuron cell survival. These cells control muscle function. Without SMN protein, motor neuron cells die, causing muscles to become so weak that breathing, eating, and moving become difficult, and the condition is likely to become life threatening in its most severe forms.

### **The role of the vector**

ZOLGENSMA is made up of a new, working copy of a human *SMN* gene that is placed inside a vector. A vector's job is to deliver the new, working *SMN* gene to the motor neuron cells in the body.

### **Delivery of the *SMN* gene**

The vector that delivers the *SMN* gene is made from a virus called adeno-associated virus 9, or AAV9. This type of virus does not make people sick. To make the vector, the DNA of the virus is removed so that the new *SMN* gene can be put inside. Vectors are used because they can travel throughout the body and deliver the new, working gene to the cells where it is needed.

### **Production of SMN protein**

When the new, working gene reaches its destination, it is ready to tell the motor neuron cells to start making SMN protein. This happens throughout the body, with many vectors delivering a new, working copy of the *SMN* gene to motor neuron cells. The new gene does not become part of the child's DNA.

### **Motor neuron cells maintained**

With the motor neuron cells now able to make sufficient SMN protein, motor neuron cells that have not died may survive, function, and be maintained.

## Patients treated after SMA symptoms appeared (symptomatic)

### **STR1VE study (completed)**

This study followed the START study.

**Participants:** 22\* patients with SMA Type 1 (had 2 copies of *SMN2* backup gene, showed symptoms of SMA, and were 6 months of age or younger at the time of infusion)

**Goal:** Establish efficacy and safety of ZOLGENSMA

\*One patient was initially not part of the data set but is included in the final data analysis.

### **START study (completed)**

This was the first study of ZOLGENSMA.

**Participants:** 15 patients with SMA Type 1 (had 2 copies of *SMN2* backup gene, showed symptoms of SMA, and were 8 months of age or younger at the time of infusion)

**Goal:** Establish safety and determine the appropriate dose of ZOLGENSMA

### **START LTFU study (ongoing)**

In addition, participants in the START study were invited to voluntarily enroll in a long-term follow-up (LTFU). The ongoing 15-year observational study enrolled 13 of 15 patients from the START study and is intended to monitor ongoing safety.

# Gene doping

Repoxygen is a new way to artificially enhance an athlete's performance — one that is hard to detect and with potentially permanent effects

WORLD  
ANTI-DOPING  
AGENCY

## How it works

Repoxygen was developed as a gene therapy treatment for severe anemia. A patient is injected with a harmless virus carrying a modified gene that encodes erythropoietin, a protein that boosts red blood cell production. The host's cells can translate that gene into active proteins as if the foreign gene were the cells' own.

### 1 Delivery

DNA packaged in a virus is injected into the athlete and flows through the bloodstream into muscle.

**Danger:** Altered viruses can trigger dangerous reactions from the immune system.

**Alternatives:** Viruses are not the only way to deliver performance-enhancing genes to cells. Fat molecules or naked DNA can be injected directly into muscle.

### 2 Change

Viruses bind to muscle cells and deposit the foreign gene inside, where it integrates into the cell's chromosomes. The gene stimulates the production of the protein erythropoietin (EPO).

**Danger:** Inserting foreign DNA can damage the cell's own genes, risking cancer.

**Detection:** Presence of a foreign gene in the athlete's DNA.

## Other gene doping possibilities

■ In 1988, H. Lee Sweeney and colleagues at the University of Pennsylvania School of Medicine injected mice with a virus carrying a gene that boosted production of insulin-growth factor 1 (IGF-1). The injected mice had 15% more muscle mass than untreated mice.

■ In 2004, Ronald Evans and colleagues at California's Salk Institute for Biological Studies engineered mice to have extra copies of the gene encoding a protein called peroxisome proliferator-activated receptor delta (PPAR-delta). These mice could run twice as far as unaltered mice.

### 3 Dispersal

Erythropoietin (EPO), produced by the altered muscle cells, flows through the bloodstream to bone marrow, stimulating production of red blood cells, the body's main transporter of oxygen.

**Detection:** Changes in the concentration of multiple proteins in the blood or urine.

### 4 Enhancement

Extra red blood cells flow throughout the athlete's body, increasing oxygen capacity and, hence, endurance.

Geni:

-EPO

-IGF1

Miostatina

# CAR-T cell therapy: Engineering Patients' Immune Cells to Treat Their Cancers

Chimeric antigen receptors (CARs)

Adoptive cell transfer is like “giving patients a living drug,”

Immunotherapy—therapies that harness the power of a patient's immune system to combat their disease,

**One approach :  
immunotherapy involves  
engineering patients'  
own immune cells to  
recognize and attack  
their tumors-remarkable  
responses in patients  
with advanced cancer.**

# Overview of CAR T-cell therapy in the clinic.

© 2017 Terese Winslow LLC  
U.S. Govt. has certain rights

A patient's T cells are harvested through leukapheresis, followed by T-cell activation on antibody-coated beads. The activated T cells are then genetically reprogrammed *ex vivo* by transduction with a construct encoding the CAR, and the CAR T cells are further expanded *ex vivo*. When the CAR T-cell product has been prepared and has passed all quality control testing, the patient receives lymphodepleting chemotherapy and CAR T-cell infusion. © Novartis Pharmaceuticals.

## Le CAR-T autorizzate.

Le terapie CAR-T rappresentano la prima forma di terapia genica approvata per il trattamento della **leucemia linfoblastica B** e di alcune forme aggressive di **linfoma non-Hodgkin**.

- **Kymriah** (tisagenlecleucel), autorizzato il 22 agosto 2018
- **Yescarta** (axicabtagene ciloleucel), autorizzato il 23 agosto 2018,

indicate per il trattamento di: – pazienti pediatrici e giovani adulti fino a 25 anni di età affetti da leucemia linfoblastica acuta a cellule B che non abbiano mai risposto alla chemioterapia, o che siano in recidiva dopo trapianto di cellule staminali emopoietiche allogeniche o dopo almeno 2 linee di chemioterapia (Kymriah); pazienti con linfoma diffuso a grandi cellule B o DLBCL (Kymriah e Yescarta) /linfoma primitivo del mediastino a cellule B o PMBCL (Yescarta) già sottoposti ad almeno 2 linee di terapia sistemica.

## CAR-T: efficacia e sicurezza del trattamento

Rispetto alle terapie “convenzionali”, le CAR-T permettono di ottenere remissioni complete anche in fasi di malattia molto avanzate. Inoltre, a un anno dall’infusione di CAR-T, la maggior parte dei pazienti che ha ottenuto una remissione è ancora viva e libera da malattia.

These scans show a 62-year-old man with **non-Hodgkin lymphoma**, at left in **December 2015**, and **three months after treatment with Kite Pharma's experimental gene therapy at MD Anderson Cancer Center in Houston**. The treatment, called CAR-T cell therapy, turns a patient's own blood cells into specialized cancer killers. It worked in a study, with more than one third of very sick lymphoma patients showing no sign of disease six months after a single treatment, its maker said Tuesday, Feb. 28, 2017. The scans are from a presentation by Drs. Fred Locke and Sattva Neelapu, provided by the American Society for Blood and Marrow Transplantation and Kite. (ASBMT/Kite Pharma via AP)
