# Exercises Lecture III: Random numbers with non uniform distributions; simulations of simple random processes

## homework: n. 1,3,4

# 1. Random numbers with non uniform distributions: Inverse Transformation Method

- (a) With the Inverse Transformation Method we can generate random numbers according to the exponential distribution  $f(z) = \lambda e^{-\lambda z}$ , starting from random numbers with uniform distribution: if x is the random variable with uniform distribution in [0,1], then z = -ln(x) is distributed according to  $e^{-z}$ . Write a code implementing the algorithm. An example is given in expdev.f90.
- (b) Check—doing a histogram—that the random variate z generated with that algorithm is actually exponentially distributed.
  (What is convenient to plot in order to check this behavior? Hint: with gnuplot you can print the log of your data (e.g., suppose you saved the values of z in column 1 and its frequency in column 2, plot with u 1:(log(\$2)) or u 1:(log10(\$2)) )).
- (c) With gnuplot you can also do the fit of the histogram with an exponential function using the least-square method, with  $\lambda$  as fitting parameter. Check whether you get the expected value of  $\lambda$ . (It is convenient to make a semilog plot as suggested above and then make a least-square linear fit; the slope is  $\lambda$ )

Remember that with the method of the least-square fit we get for a linear regression: y = ax + b:

$$a = \frac{\overline{xy} - \overline{yy}}{(\Delta x)^2}; \qquad b = \overline{y} - a\overline{x}$$

where  $(\Delta x)^2 = \overline{x^2} - \overline{x}^2$  (other definitions are trivial ...).

## 2. Random numbers with non uniform distributions: comparison between different algorithms

Suppose you want to generate a random variate x in (-1,1) with distribution

$$p(x) = \frac{1}{\pi} (1 - x^2)^{-1/2}.$$

Consider both methods suggested below, do the histograms and check that both methods give correct results.

- (a) From the Inverse Transformation Method: generate a random number U with uniform distribution in [0,1] and consider  $x = \sin \pi (2U - 1)$ .
- (b) Generate two random numbers U and V with uniform distribution in [0,1]. Disregard them if  $U^2 + V^2 > 1$ . Otherwise consider

$$x=\frac{U^2-V^2}{U^2+V^2}$$

Note 1: the last method has the advantage of using only elementary operations.

Note 2: since x is also negative, pay attention to the algorithm used to make the histogram; you should notice the difference between the intrinsic functions int and nint; see also floor. From Chapman's book:

```
AINT(A,KIND):
                Real elemental function
- Returns A truncated to a whole number.
AINT(A) is the largest integer which is smaller than |A|, with the sign of A.
For example, AINT(3.7) is 3.0, and AINT(-3.7) is -3.0.
  Argument A is Real; optional argument KIND is Integer
ANINT(A,KIND):
                Real elemental function
- Returns the nearest whole number to A.
For example, ANINT(3.7) is 4.0, and AINT(-3.7) is -4.0.
- Argument A is Real; optional argument KIND is Integer
FLOOR(A,KIND):
                Integer elemental function
- Returns the largest integer < or = A.
For example, FLOOR(3.7) is 3, and FLOOR(-3.7) is -4.
- Argument A is Real of any kind; optional argument KIND is Integer
  Argument KIND is only available in Fortran 95
NINT(A[,KIND])
- Integer elemental function
- Returns the nearest integer to the real value A.
- A is Real
```

## 3. Random numbers with gaussian distribution: Box-Muller algorithm

Consider the Box-Muller algorithm to generate a random number gaussian distribution (see for instance **boxmuller.f90**; the **gasdev** subroutine used inside is similar to what you can find in "Numerical Recipes": it gives a gaussian distribution with  $\sigma = 1$  and average  $\mu = 0$ ). Do a histogram of the data generated, calculate *numerically* from the sequence the average value and the variance, check with the expected results.

#### 4. Simulation of radioactive decay

- (a) Write a program for a numerical simulation of the radioactive decay, with a decay parameter  $\lambda$  in input. (See for instance decay.f90).
- (b) Use the code with "reasonable" values of the parameters (e.g., N(0) about 1000) and save N(t) in a data file. Check whether N(t) = N(0)e<sup>-λt</sup> as expected. (*Hint: As for the exercise 1, you could make use of a least-square fit by considering* ln N(t) vs. t, i.e. the relationship in a semilog form in order to manage a linear fit.)
- (c) Change N(0) (100 or less; 10000 or more). What do you see?

Notice that in decay.f90 the upper bound of the inner loop (nleft) is changed within the execution of the loop; but in the execution the loop goes on up to the nleft set at the beginning of the loop; this ensures that the implementation of the algorithm is correct. See the programs checkloop.f90 and decay\_checkloop.f90 in the same directory.

#### 5. Random deviates with other distributions (Optional)

```
You can try t_random.f90 which uses the module random.f90 to generate random deviates with other distributions. Remember to compile first the module: g95 (or gfortran) random.f90 t_random.f90
```

#### 

```
! expdev.f90
program test_expdev
