

Astrofisica Nucleare e Subnucleare  
“X-ray” Astrophysics

# **Strumentazioni per l'astrofisica**

(prima parte)

## **Rivelazione di raggi X/ $\gamma$ in condizioni astronomiche**

**partly adapted from G. Malaguti's Lessons**  
*Istituto Nazionale di Astrofisica (INAF) IASF-Bologna*

# Scanning with Slat Collimators

- **Imaging the sky with non-imaging X-ray instruments as a goal**
- **Linear scanning means position is determined in one direction**
- **At least a second scanning, preferentially in the direction perpendicular to the previous one**
- **First all-sky survey in X-rays by Uhuru (1970-72): 2 prop. counters with metal collimators ( $0.5^\circ \times 5^\circ$ ,  $5^\circ \times 5^\circ$  FWHM )**

# Scanning Grid Collimators

- Two or more plane (“grid” of absorbing rods) collimators to improve angular resolution
- Higher resolution with three or more grids (e.g., 4 in HEAO-1 A-3 experiment)
- Two-dimensional measurements need scans in two or more directions

Double-grid collimator  
Transmission Function of triangular shape  
Angular resolution:  $d/D$

# Sensibilità - 1

- **Sensibilità = flusso minimo rivelabile**
  - **Emissione nel continuo:** fotoni  $\text{cm}^{-2} \text{s}^{-1} \text{keV}^{-1}$
  - **Emissione di righe:** fotoni  $\text{cm}^{-2} \text{s}^{-1}$
- **$C_S$  = Tasso di conteggi di sorgente**
- **$C_{Bkg}$  = Tasso di conteggi di fondo**  
**assumendo una statistica poissoniana**

$$SNR = n_\sigma = \frac{C_S}{\sqrt{C_S + C_{Bkg}}}$$

In realta' quello che si misura e'  $(S+B)-B$  in un dato intervallo di tempo

$$\begin{aligned} S &= (S + B) - B \longrightarrow \sigma_S^2 = \sigma_{S+B}^2 + \sigma_B^2 = \\ &= (\sqrt{(S + B)})^2 + (\sqrt{B})^2 = S + B + B = S + 2B \\ SNR &= S / \sigma_S = S / \sqrt{(S + 2B)} \end{aligned}$$

# Sensibilità – 2 – “basic” dependencies

$$S = \varepsilon A T \Delta E F_{src}$$

$$B = A T \Delta E F_{bkg}$$

$\varepsilon$ =efficienza di rivelazione fotoni della sorgente  
 $A$ =area efficace  
 $T$ =tempo di esposizione  
 $\Delta E$ =banda energetica  
 $F_{src}$ =flusso della sorgente  
 $F_{bkg}$ =fondo strumentale

$$B \ll \varepsilon F_{src}$$

$$SNR = \frac{S}{\sqrt{S + 2B}} \approx \sqrt{S} \propto \sqrt{F_{src} T}$$

the source dominates the signal

$$B \gg \varepsilon F_{src}$$

$$SNR = \frac{S}{\sqrt{S + 2B}} \approx S / \sqrt{2B} \propto \sqrt{T} (F_{src} / \sqrt{2F_{bkg}})$$

Backg-dominated obsn.

$$SNR = n_{\sigma} \approx \frac{\varepsilon \cdot A \cdot T \cdot \Delta E \cdot F}{\sqrt{A \cdot T \cdot \Delta E \cdot B}} \rightarrow F_{Min} = \frac{n_{\sigma}}{\varepsilon} \sqrt{\frac{B}{A \cdot T \cdot \Delta E}}$$

to give an idea of the main dependencies of the limiting flux (sensitivity)

In the “real world”, the background is not only instrumental but also cosmic

S=source flux density [counts/m<sup>2</sup> s]

A=area of the detector

Ω=solid angle subtended by the beam of the telescope on the sky

B<sub>1</sub>=instrumental (particle) background [counts/s]

B<sub>2</sub>=cosmic background (XRB) [phot/m<sup>2</sup> s ster]

T=exposure time

**SOURCE**=S×A×T (photons related to the source)

**BACKGROUND**=B<sub>1</sub>×T + B<sub>2</sub>×A×Ω×T (photons related to the backgrounds)

$$N = \sqrt{(B_1 + B_2 A \Omega) \times T}$$

$$S/N = \frac{SAT}{\sqrt{(B_1 + B_2 A \Omega) \times T}} = \frac{SA^{1/2}T^{1/2}}{\sqrt{\left(\frac{B_1}{A}\right) + \Omega B_2}}$$

$$S/N = 5 \Rightarrow S_{\min} = 5 \sqrt{\frac{B_1 / A + \Omega B_2}{AT}}$$

# Focalizzazione vs collimazione

Proper imaging of X-rays below 20-40 keV

$A_d$  = PSF projected on the focal plane

$$F_{\min} \approx n_{\sigma} \frac{\sqrt{2B}}{\sqrt{A_{\text{det}} T_{\text{int}} \Delta E}}$$

$$F_{\min} \approx n_{\sigma} \frac{\sqrt{BA_d}}{A_{\text{eff}} \sqrt{T_{\text{int}} \Delta E}}$$

**Sistema collimato:** limita la regione di cielo da cui puo' provenire un segnale, (quindi limita il background), non incrementandone la "densita"

**Sistema focalizzato:** fa corrispondere ad ogni sorgente un punto nel piano focale, e "concentra" il segnale, producendo un'immagine

$$C_B = B A_d \Delta E \Delta t$$

Background counts from a collimated telescope with detector area  $A_d$ , sensitive over the band  $\Delta E$ , in a time interval  $\Delta t$

$$\sigma(C_B) = C_B^{1/2}$$

The counts obey the Poisson statistics

$$C_S = S_E A_d \Delta E \Delta t \eta_E$$

Source counts collected from a source with flux  $S_E$  in the same conditions ( $QE = \eta_E$ )

$$C_{\text{meas}} = (C_S + C_B) - C_B$$

Measured counts (backg-subtracted)

$$\sigma^2(C_{\text{meas}}) = 2\sigma^2(C_B)$$

Background dominates fluctuations

$$S/N = n_\sigma = \frac{C_S}{\sqrt{2C_B}} = \frac{S_E A_d \Delta E \Delta t \eta_E}{\sqrt{2B A_d \Delta E \Delta t}}$$
$$S_{E,\text{min}} = \frac{n_\sigma \sqrt{2B}}{\eta_E \sqrt{A_d \Delta t \Delta E}}$$

# X-Ray Mirrors

## *Why do we use X-ray optics*

- To achieve the best 2-dim angular resolution
  - To distinguish nearby sources or different regions of the same source
  - To perform morphological studies
- As a collector to “gather” weak fluxes (case of limited photon statistics)
- As a concentrator, so that the image photons may interact in a small region of the detector, thus limiting the influence of the background
- To serve with high spectral resolution dispersive spectrometers such as transmission or reflection gratings
- To simultaneously measure both the source(s) of interest and the contaminating background in other (source-free) regions of the detector

## *X-ray optical constants*

- X-rays are hard to refract or reflect: the refractive index of all materials in X-rays is very close to 1 and only slightly less than 1 → X-rays are above the characteristic energy of bonded e<sup>-</sup> in atoms
- complex index of refraction of the reflector to describe the interaction X-rays /matter (see, for a review, Aschembach et al. 1985, Rep. Prog. Phys. 48, 579)

$$n=1-\delta+i\beta$$

where  $\delta$  describes the phase change and  
 $\beta$  accounts for the absorption

$\delta$  and  $\beta$  depend on the wavelength

- the amplitude of reflection is described by the Fresnel's equations

Snell's Law of Refraction:  
relationship between the angles of incidence  
and refraction in a medium

$$n_1 \sin \theta_1 = n_2 \sin \theta_2$$

$$n_1 = 1, n_2 = (1 - \delta) \rightarrow \sin \phi_i = (1 - \delta) \sin \phi_r$$

$$\vartheta = (\pi / 2) - \phi$$

$$\cos(90 - \phi_i) = \cos \vartheta_i = (1 - \delta) \cos(90 - \phi_r) = (1 - \delta) \cos \vartheta_r$$

$$\Rightarrow \cos \vartheta_i = \cos \vartheta_r (1 - \delta)$$

Total reflection if no real solution for  $\vartheta_r$   
 $\delta > 0, \cos \theta_r \leq 1 \rightarrow$  There is a **critical angle**  $\theta_c$  below which refraction is impossible  
 and total external reflection occurs (grazing angle,  $\theta_i = \theta_c$ )

Extreme case for  
low  $\theta_r$  values

$$1 = \cos \vartheta_r = \cos \vartheta_c / (1 - \delta) \rightarrow \cos \vartheta_c = 1 - \delta$$

## Total X-ray reflection at grazing incidence

- Real part of  $n$  slightly less than unity for matter at X-rays, =1 in vacuum (total external reflection);  $\delta \ll 1$

- Snell's law ( $n_1 \cos\theta_1 = n_2 \cos\theta_2$ ) to find a critical angle for total reflection

- (Total) external reflection in vacuum for angles  $<$  critical angle:  $\cos\theta_{crit} = 1 - \delta$

- X-ray partially reflected also for  $\theta > \theta_{crit}$ ; also, some absorption in the material

- $\cos(\theta_{crit}) = 1 - \theta_{crit}^2/2 = 1 - \delta \xrightarrow{\text{low angles}} \theta_{crit} = \sqrt{2\delta}$

- Far from fluorescent edges:

$$\delta \approx \frac{N_0 Z r_e \rho \lambda^2}{2\pi A}$$

where  $N_0$ =Avogadro's number

$Z$ =atomic number

$r_e$ =electron radius

$\rho$ =density

$\lambda$ =wavelength of the incoming photon

$A$ =atomic weight

Critical angle:

- Inversely dependent on energy
- Higher  $Z$  materials reflect higher energies, for a fixed grazing angle
- Higher  $Z$  materials have a larger critical angle at any energy

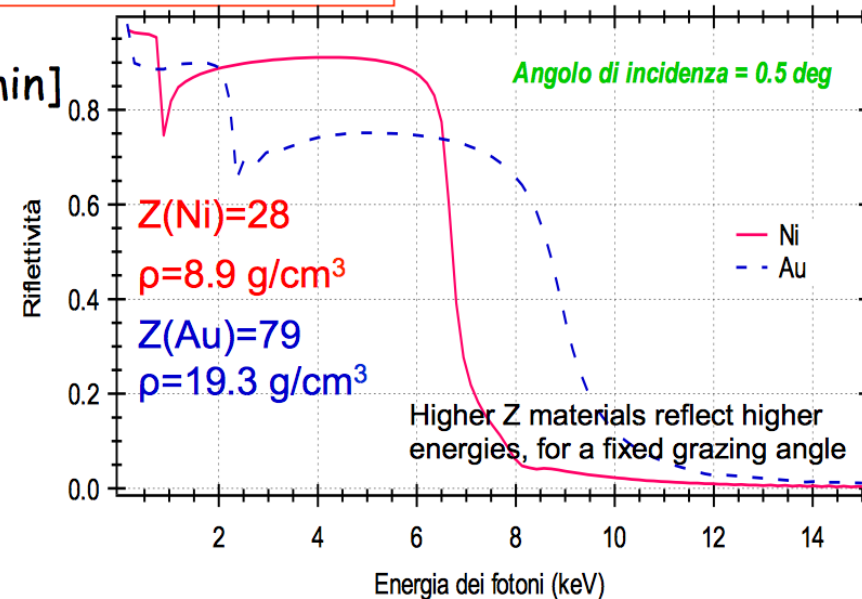

- For heavy elements,  $Z/A \approx 0.5$ , and if  $\delta \ll 1$ :

$$\theta_{crit} \approx \sqrt{2\delta} \approx 5.6\lambda\sqrt{\rho}$$

where  $\lambda[\text{\AA}]$  and  $\rho[\text{g/cm}^3]$ , and  $\theta[\text{arcmin}]$

$$\theta_{crit} \propto \sqrt{\rho} / E$$

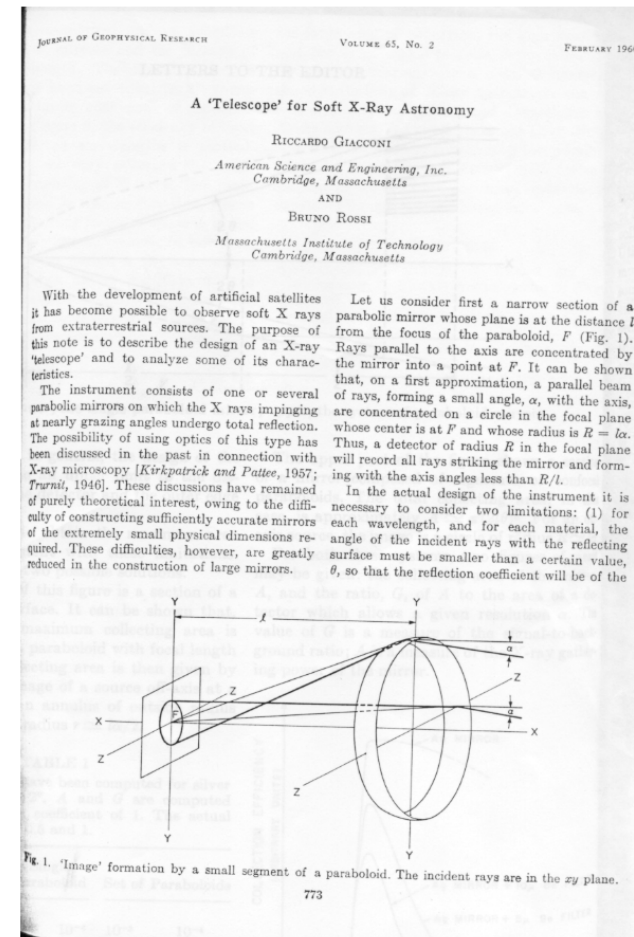

- Some reflectivity is lost due to scattering related to the presence of micro-roughness at the surface
- Use of heavy materials (but attention at the absorption edges...)

# X-ray mirrors with parabolic profile

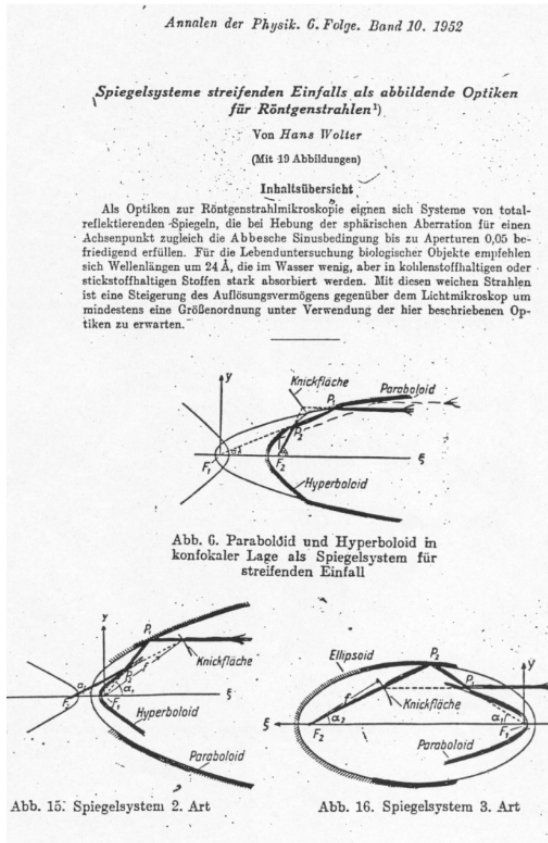

- perfect on-axis focusing
- off-axis images strongly affected by coma

## Telescopes and instruments

### Dispersing elements – Bragg Crystal spectroscopy/1

(more details on dispersive spectrometers: Giacconi & Gursky, p. 81-90)

The reflection of X-rays from a crystal lattice follows the Bragg's law, and therefore the name Bragg spectrometer is usually given to the device with this kind of reflection grating.

Here the macroscopic shaping (grooves) of a metallic plate, which is used in longer wavelengths, is replaced by a material with regular lattice structure of atoms (crystal material). The reflection takes place by the same principle as from a macroscopic lattice, leading to a wavelength-dispersed output from a white light input.

The lattice of the crystal forms a 3-dimensional diffraction array which reflects X-rays of wavelength  $\lambda$  within a narrow range of wavelength satisfying the Bragg condition

$$n \lambda = 2d \sin\theta \quad , \quad n = 1, 2, 3, \dots \text{ (order of diffraction)}$$

where  $d$  is the crystal lattice spacing.  
In practice, order  $n=1$  is used.

# X-ray spectroscopy

## Dispersing elements – Diffraction gratings/1

Ordinary diffraction gratings can also be used from from long wavelengths up to soft X-rays (< 1 keV, in practice).

The grating equation is

$$n \lambda = (1/N) (\sin \theta - \sin \theta_0), \quad n = 1, 2, 3, \dots \text{ (order of diffraction)}$$

where  $N$  is the grating constant (lines/cm),  $\theta$  is the diffraction angle and  $\theta_0$  is the angle of incidence. For X-rays this is usually rearranged in form valid for small angles

$$n \lambda N = \theta - \theta_0$$

There are two geometries usually applied in X-ray optics,

### 1. Conventional Johann mount geometry

### 2. Curved grating producing a line image

# ROSAT results

The ROSAT All-Sky Survey Bright Source Catalogue (RASS-BSC, revision 1RXS) is derived from the all-sky survey performed during the first half year of the ROSAT mission in 1990/91. 18,811 sources are catalogued, with a limiting ROSAT PSPC countrate of 0.05 cts/s in the 0.1-2.4 keV energy band. 34

# ROSAT

<http://www.mpe.mpg.de/xray/wave/rosat/>

The scientific payload consists two coalligned scientific experiments, the [The X-Ray Telescope](#) which is used in conjunction with one of the focal plane instruments:

- [The Position Sensitive Proportional Counter](#)
- [The High Resolution Imager](#)

and the [The Wide Field Camera](#) which has its own mirror system and star sensor.

ROSAT provides a  $\sim 2$  degree diameter field of view with the PSPC in the focal plane, and  $\sim 40$  arcmin diameter field of view with the HRI in the focal plane. The ROSAT mission began with a six-month, all-sky PSPC survey, after which the satellite began a series of pointed observations that continued for the duration of the project.

# ROSAT results

The ROSAT All-Sky Survey Bright Source Catalogue (RASS-BSC, revision 1RXS) is derived from the all-sky survey performed during the first half year of the ROSAT mission in 1990/91. 18,811 sources are catalogued, with a limiting ROSAT PSPC countrate of 0.05 cts/s in the 0.1-2.4 keV energy band. 36

# RXTE

<http://heasarc.gsfc.nasa.gov/docs/xte/xtegif.html>

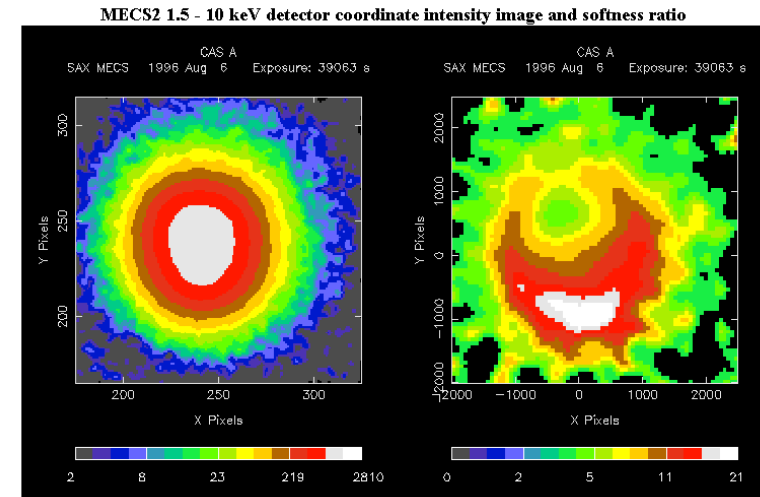

The lowest-mass known black hole belongs to a binary system named XTE J1650-500. The black hole has about 3.8 times the mass of our sun, and is orbited by a companion star

The Rossi X-ray Timing Explorer (RXTE) was launched on December 30, 1995. RXTE features unprecedented time resolution in combination with moderate spectral resolution to explore the variability of X-ray sources. Time scales from microseconds to months are covered in an instantaneous spectral range from 2 to 250 keV. Originally designed for a required lifetime of two years with a goal of five, it operated up to 2012

# BeppoSAX

<http://www.asdc.asi.it/bepposax>

- Energy Range 0.1 to 200 keV
- Imaging capabilities (1') in the range of 0.1-10 keV.
- High energy (3-300 keV)
- Narrow fields and point in the same direction (Narrow Field Instruments, NFI).
- Monitoring large regions of the sky with a resolution of 5' in the range 2-30 keV
  - two coded mask proportional counters pointing in diametrically opposed directions perpendicular to the NFI
- Anticoincidence scintillator shields of the PDS will be used as a gamma-ray burst monitor in the range 60-600 keV.

# BeppoSAX results

The Galactic Centre has been observed with the Beppo SAX Wide Field Camera 1 (WFC1) in August 1996. Here an image is shown of the 40 degrees by 40. The observation period was from 22-8-1996 07.54 UT through to 23-8-1996 11.38 UT, while the effective exposure totalled about 51 kiloseconds. The number of accepted events was  $1.7955 \times 10^7$  in the energy range of 5.4 - 11.3 keV. The legenda for the galactic centre source indicated with a yellow star (1E1743.1-2843), is given at lower right in the image.

To our knowledge this is the largest field ever imaged in X-rays in a single pointing.

# X-ray science highlights

This image provides a view of the activity in the inner region around the Crab Nebula pulsar, a rapidly rotating neutron star seen as a bright white dot near the center of the images.

A wisp can be seen moving outward at half the speed of light from the upper right of the inner ring around the pulsar. The wisp appears to merge with a larger outer ring that is visible in both X-ray and optical images.

- The inner X-ray ring consists of about two dozen knots that form, brighten and fade. As a high-speed wind of matter and antimatter particles from the pulsar plows into the surrounding nebula, it creates a shock wave and forms the inner ring. Energetic shocked particles move outward to brighten the outer ring and produce an extended X-ray glow.

# X-ray science highlights

This close-up of M87 shows the region surrounding the jet of high-energy particles in more detail. The jet is thought to be pointed at a small angle to the line of sight, out of the plane of the image. This jet may be only the latest in a series of jets that have been produced as magnetized gas spirals in a disk toward the supermassive black hole

# X-ray science highlights

This image shows a computer simulation of a large volume of the Universe. An XMM-Newton X-ray image of a real galaxy cluster from the study is superimposed to illustrate the formation of galaxy clusters in the densest parts of the universe.

# Dark Matter and Cosmo Simulations

## Welcome

The Illustris project is a large cosmological simulation of galaxy formation, completed in late 2013, using a state of the art numerical code and a comprehensive physical model. Building on several years of effort by members of the collaboration, the Illustris simulation represents an unprecedented combination of high resolution, total volume, and physical fidelity. The [About](#) page contains detailed descriptions of the project, for both the general public and researchers in the field.

On this website we present the scientific motivation behind the project, a list of the collaboration members, key results and references, movies and images created from the simulation data, information on upcoming public data access, and tools for interactive data exploration. The short video below is a compilation made from some of the movies available on the [Media](#) page.

### Abstract

We present a review of the current state of the art of cosmological dark matter simulations, with particular emphasis on the implications for dark matter detection efforts and studies of dark energy. This review is intended both for particle physicists, who may find the cosmological simulation literature opaque or confusing, and for astro-physicists, who may not be familiar with the role of simulations for observational and experimental probes of dark matter and dark energy. Our work is complementary to the contribution by M. Baldi in this issue, which focuses on the treatment of dark energy and cosmic acceleration in dedicated N-body simulations.

Truly massive dark matter-only simulations are being conducted on national supercomputing centers, employing from several billion to over half a trillion particles to simulate the formation and evolution of cosmologically representative volumes (cosmic scale) or to zoom in on individual halos (cluster and galactic scale). These simulations cost millions of core-hours, require tens to hundreds of terabytes of memory, and use up to petabytes of disk storage. Predictions from such simulations touch on almost every aspect of dark matter and dark energy studies, and we give a comprehensive overview of this connection. We also discuss the limitations of the cold and collisionless DM-only approach, and describe in some detail efforts to include different particle physics as well as baryonic physics in cosmological galaxy formation simulations, including a discussion of recent results highlighting how the distribution of dark matter in halos may be altered. We end with an outlook for the next decade, presenting our view of how the field can be expected to progress.

# Suzaku

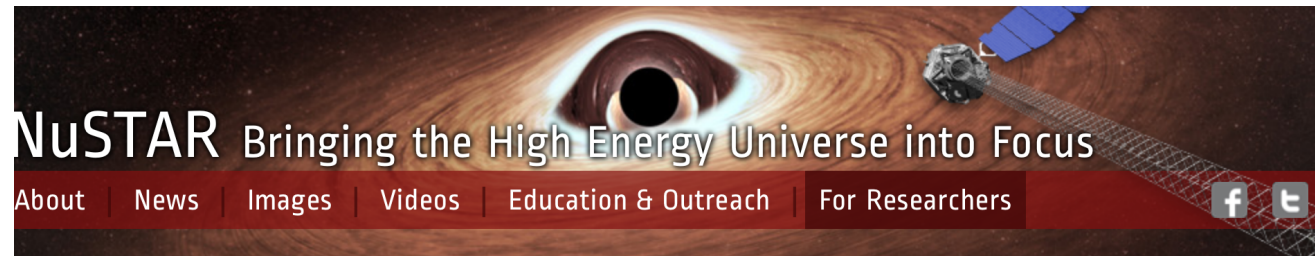

- Suzaku launched on July 10, 2005. Before launch it was called Astro-E2, and the name was changed to Suzaku shortly after the successful launch.
- Suzaku's four CCD cameras for low-energy X-rays and detector for high-energy X-rays continue to study the X-ray sky. In scientists' words, Suzaku is designed for "broad-band, high-sensitivity, high-resolution" spectroscopy.

<http://www.isas.jaxa.jp/e/enterp/missions/suzaku/>

# NuSTAR

- The NuSTAR (Nuclear Spectroscopic Telescope Array) mission has deployed the first orbiting telescopes to focus light in the high energy X-ray (3 - 79 keV) region of the electromagnetic spectrum. Our view of the universe in this spectral window has been limited because previous orbiting telescopes have not employed true focusing optics, but rather have used coded apertures that have intrinsically high backgrounds and limited sensitivity.

The plot shows Area (cm<sup>2</sup>) on a logarithmic y-axis (10 to 1000) versus Energy (keV) on a logarithmic x-axis (1 to 100). The legend indicates: NuSTAR (red), Chandra ACIS (green), XMM pn (blue), Swift XRT (purple), and Suzaku XIS (orange).

Energy (keV)	NuSTAR (cm <sup>2</sup> )	Chandra ACIS (cm <sup>2</sup> )	XMM pn (cm <sup>2</sup> )	Swift XRT (cm <sup>2</sup> )	Suzaku XIS (cm <sup>2</sup> )
1	~300	~300	~300	~100	~300
5	~800	~300	~800	~100	~800
10	~900	~30	~100	~10	~100
50	~100	~0	~0	~0	~0
79	~10	~0	~0	~0	~0

# MAXI

The Monitor of All-sky X-ray Image, MAXI, is the first experiment installed on the Japanese Experiment Module Exposed Facility (JEM-EF or Kibo-EF) on the International Space Station (ISS) and the first high energy astrophysical experiment placed on the space station.

The main objectives of MAXI are early detection of X-ray transient events, and monitoring the intensity fluctuation of known X-ray sources over long periods by scanning the all sky in soft and hard X-ray.

- two semi-circular arc-shaped X-ray slit cameras with wide FOVs. In the 92 minutes it takes the ISS to orbit the earth, MAXI gets a 360 deg image of the entire sky.
- two kinds of X-ray detectors, collecting events from the slit cameras: a gas proportional counters, the Gas Slit Camera (GSC; 2-30 keV), and a X-ray CCD, Solid-state Slit Camera (SSC; 0.5-12 keV).

# XRISM

## About XRISM

The X-ray Imaging and Spectroscopy Mission (XRISM) is a JAXA/NASA collaborative mission, with ESA participation, with the objective to investigate X-ray celestial objects in the Universe with high-throughput, high-resolution spectroscopy. XRISM is expected to launch in the Japanese fiscal year 2022 (TBR) on a JAXA H-IIA rocket.

## The eXTP Mission

The [enhanced X-ray Timing and Polarimetry mission \(eXTP\)](#) is a science mission designed to study the state of matter under extreme conditions of density, gravity and magnetism. Primary goals are the determination of the equation of state of matter at supra-nuclear density, the measurement of QED effects in highly magnetized star, and the study of accretion in the strong-field regime of gravity. Primary targets include isolated and binary neutron stars, strong magnetic field systems like magnetars, and stellar-mass and supermassive black holes.

The mission carries a unique and unprecedented suite of state-of-the-art scientific instruments enabling for the first time ever the simultaneous spectral-timing-polarimetry studies of cosmic sources in the energy range from 0.5-30 keV (and beyond). Key elements of the payload are:

- **the Spectroscopic Focusing Array (SFA)**: a set of 11 X-ray optics operating in the 0.5-10 keV energy band with a field-of-view (FoV) of 12 arcmin each and a total effective area of  $\sim 0.9 \text{ m}^2$  and  $0.6 \text{ m}^2$  at 2 keV and 6 keV respectively. The telescopes are equipped with Silicon Drift Detectors offering  $< 180 \text{ eV}$  spectral resolution.
- **the Large Area Detector (LAD)**: a deployable set of 640 Silicon Drift Detectors, achieving a total effective area of  $\sim 3.4 \text{ m}^2$  between 6 and 10 keV. The operational energy range is 2-30 keV and the achievable spectral resolution better than 250 eV. This is a non-imaging instrument, with the FoV limited to  $< 1^\circ$  FWHM by the usage of compact capillary plates.
- **the Polarimetry Focusing Array (PFA)**: a set of 2 X-ray telescope, achieving a total effective area of  $250 \text{ cm}^2$  at 2 keV, equipped with imaging gas pixel photoelectric polarimeters. The FoV of each telescope is 12 arcmin and the operating energy range is 2-10 keV.
- **the Wide Field Monitor (WFM)**: a set of 3 coded mask wide field units, equipped with position-sensitive Silicon Drift Detectors, covering in total a FoV of 3.7 sr and operating in the energy range 2-50 keV.
