

Landslide susceptibility analysis in Arandu area Shigar valley, CKNP (Gilgit- Baltistan- Pakistan)

CHE PARAMETRI?

As previously described, several are the parameters usable in order to define a landslide susceptibility map. For the work done, the chosen parameters are the easiest to collect:

- Geology
- tectonic structures (thrusts and faults)
- plan curvature
- slope angle
- Aspect
- drainage network
- glaciated areas
- land cover

IL METODO

To prepare the LSM, the geological and lithological conditions were previously analysed, and later the main geomorphologic parameters (slope angle, aspect and plan curvatures) computed. Furthermore, the LSM was obtained combining the different parameters in accordance with their relative influence to the landslide occurrence following the **Analytical Hierarchy Process (AHP)**. The latter rates not only the parameters, but also the classes in which each parameter is classified. The parameters, arranged in hierarchical order of priority in rows and columns, generated a pair-wise comparison matrix. **Frequency ratio (FR) method** was adopted to drive each class weight. The parameters were later combined through the **Weighted Linear Combination (WLC)** where secondary-level weights are opinion-based scores. The result is the Landslide Potential Index map (LPI) calculated using the following formula:

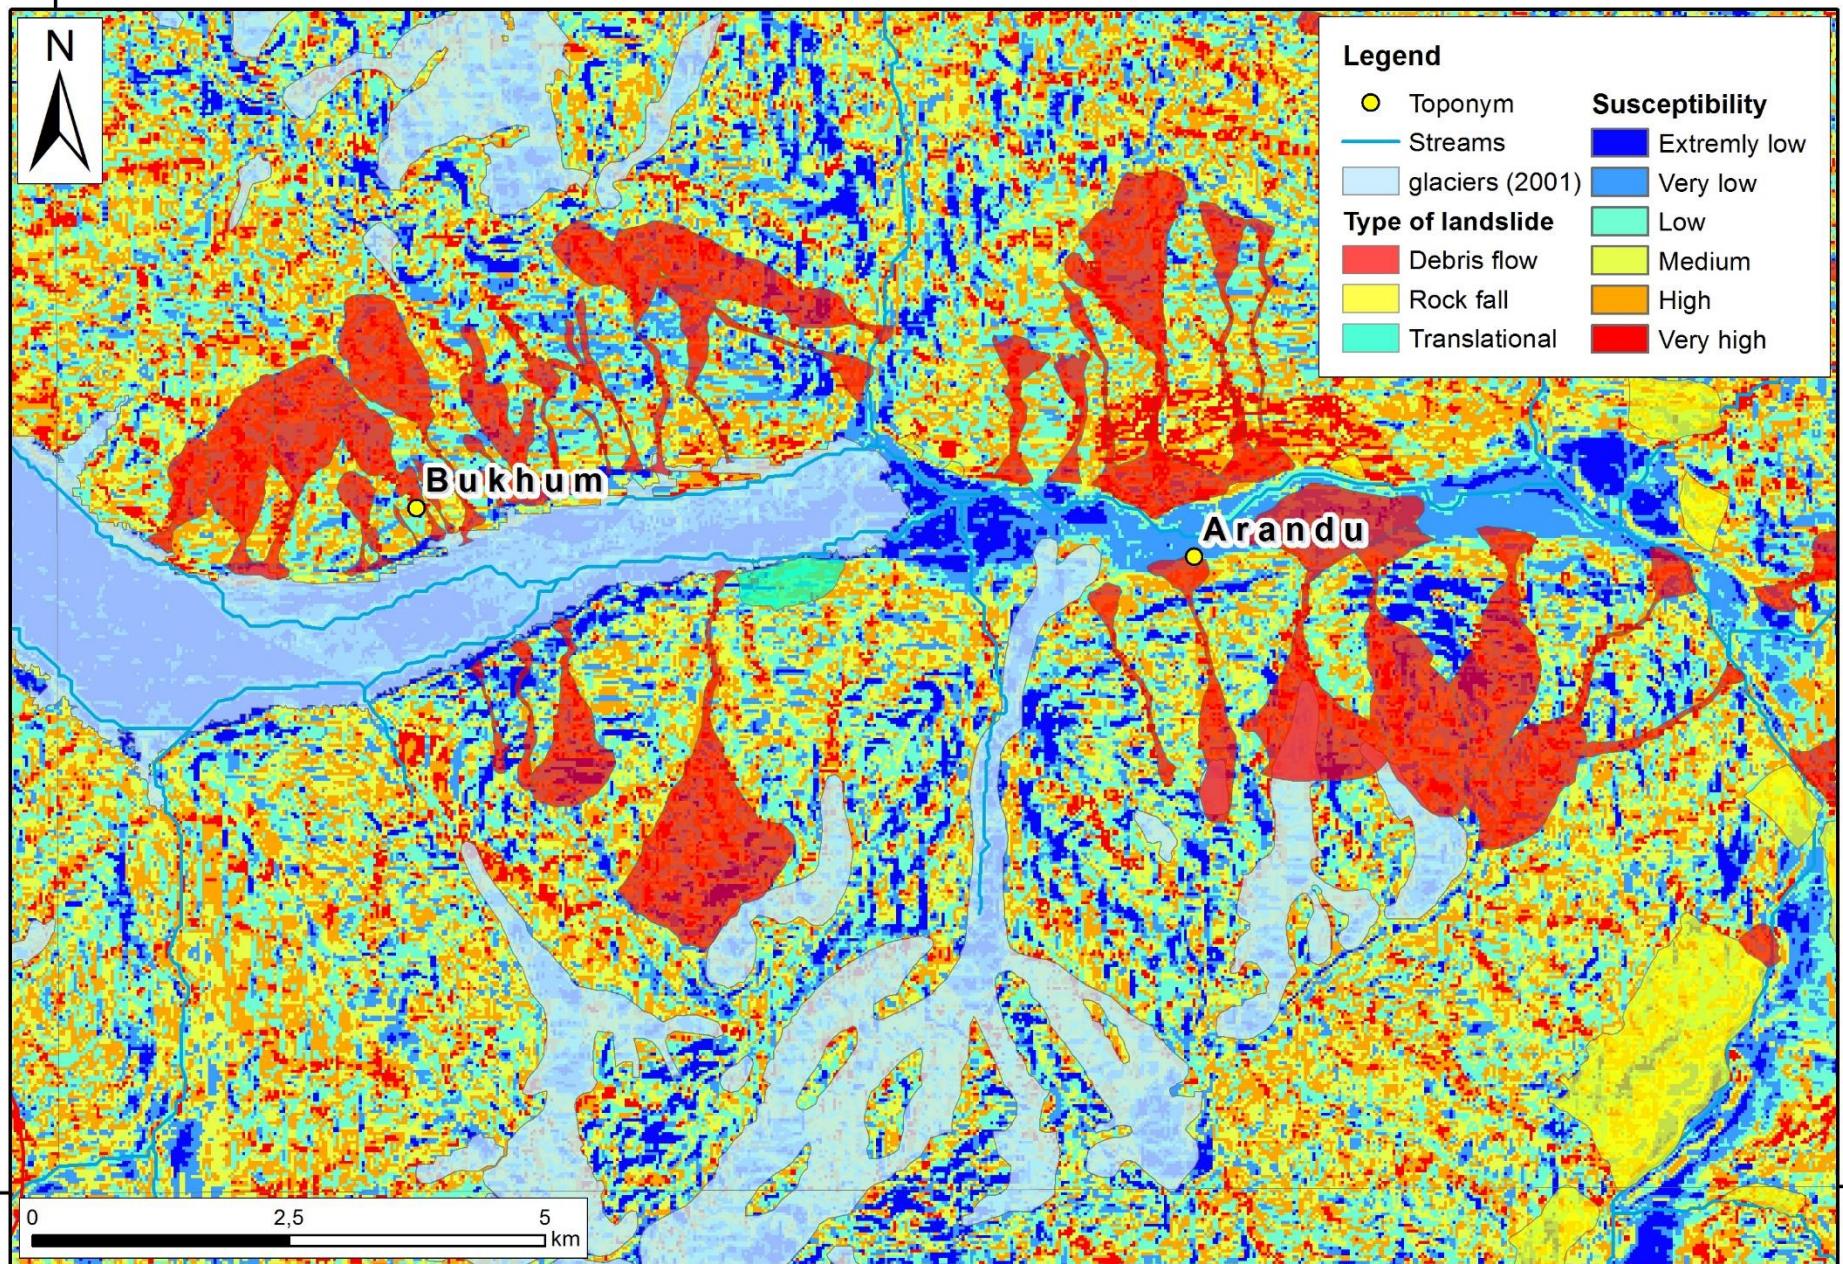

$$LPI = \sum (R_i \times W_{ij}) \quad (1)$$

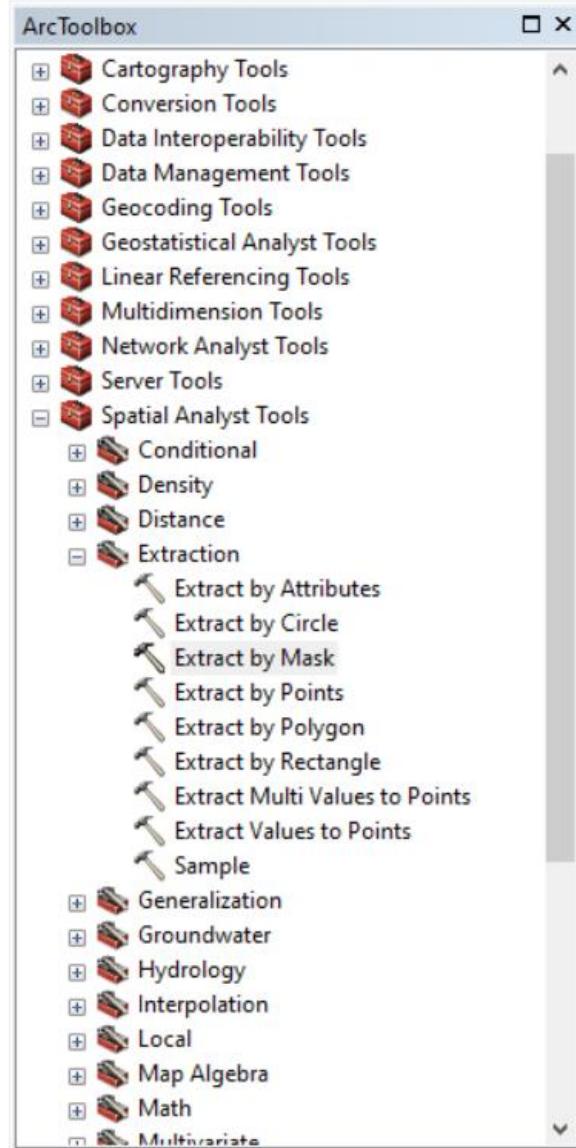

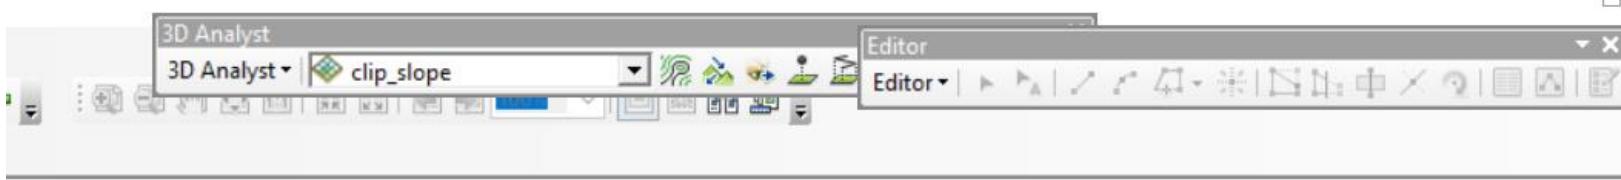

where $i = 1 - 9$, R_i is the rank for parameter i , and W_{ij} is the weight for class j of i factor.

Frequency Ratio (FR) computed for each single class. For the geology, hereafter are explained the acronyms used. cgM=Miar conglomerate; csiz=zil felsic gneiss; Ey=Old screes and eluvial deposits; gB=Baltoro granite; gcsiMB=Mangol Bulk or Basha dome; L=Landslide; Mcsi=Magmatic gneiss; mKK=Marble; mT=Tagafar limestone; sKK=Unidifferentiated metasediments

	Class	FR		Class	FR	
GEOLOGY	cgM	0,00	DISTANCE TO RIVER	0-50 m	0,54	
	csiz	1,15		50-100 m	0,63

RICLASSIFICO DIRETTAMENTE A PARTIRE DAL COMANDO *Reclassify*

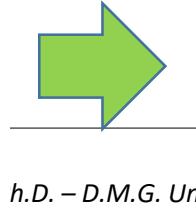

The Analytical Hierarchy Process (AHP) was used to extract the factor weights in a pairwise comparison matrix. Frequency ratio (FR) method was adopted to drive each class weight. The Weighted linear combination was used in the end to determine the landslide susceptibility index value (LSI).

Quindi riclassifico i raster tematici sulla base dei FR ottenuti
E solo successivamente moltiplico ciascun raster per il suo peso.
