Catalyst **STRUCTURE**

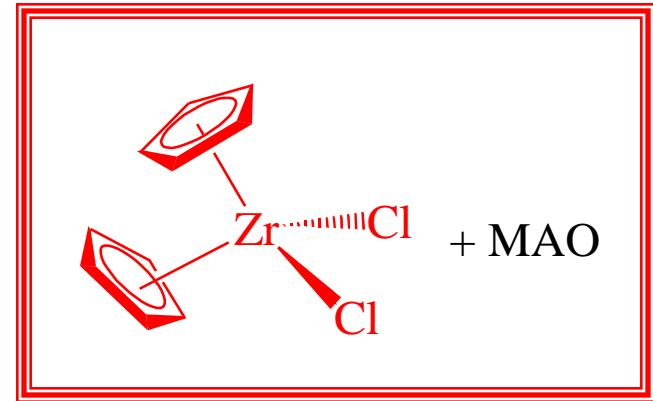

Polymerization **MECHANISM**

Polymer **STRUCTURE and PROPERTIES**

The “Metallocene Revolution”¹

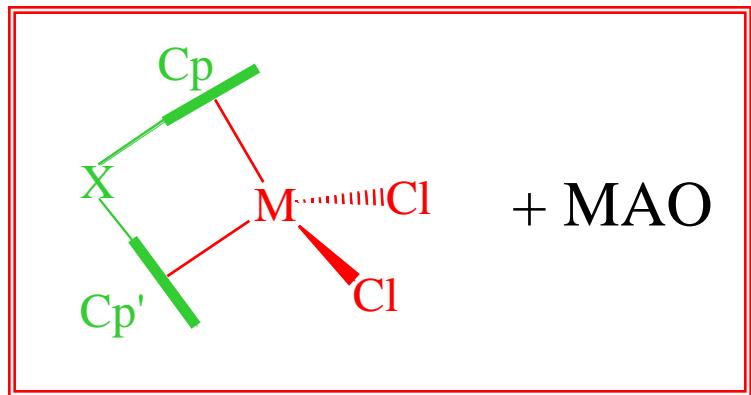

Features:

- ❖ homogeneous catalysts: 100 times more active than the conventional Ziegler-Natta (300 t PE/g Zr h);
- ❖ they catalyze the stereospecific polymerization of prochiral terminal alkenes;
- ❖ the synthesized polyolefins are featured by a narrow molecular weight distribution: Single Site Catalysts;
- ❖ branched polyolefins featured by branches of different length regularly distributed along the main chain are also obtained;
- ❖ these catalysts can be heterogenized.

Metallocene Catalysts are very versatile

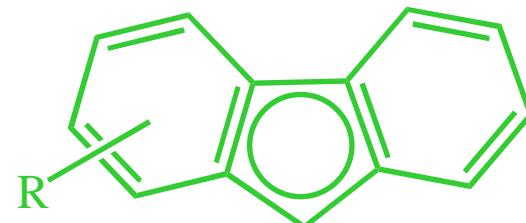

$M = Ti, Zr, Hf$

$Cp = Cp' \text{ o } Cp \neq Cp'$

$Cp \text{ e } Cp' =$

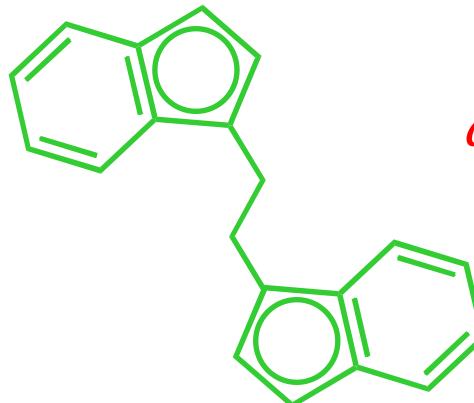

indenyl

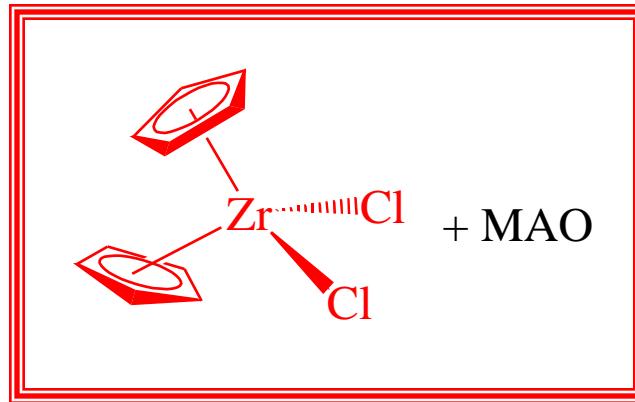

fluorenyl

$Cp-X-Cp' =$

$X = CH_2CH_2, R_2Si,$
 R_2C

ansa-metallocenes

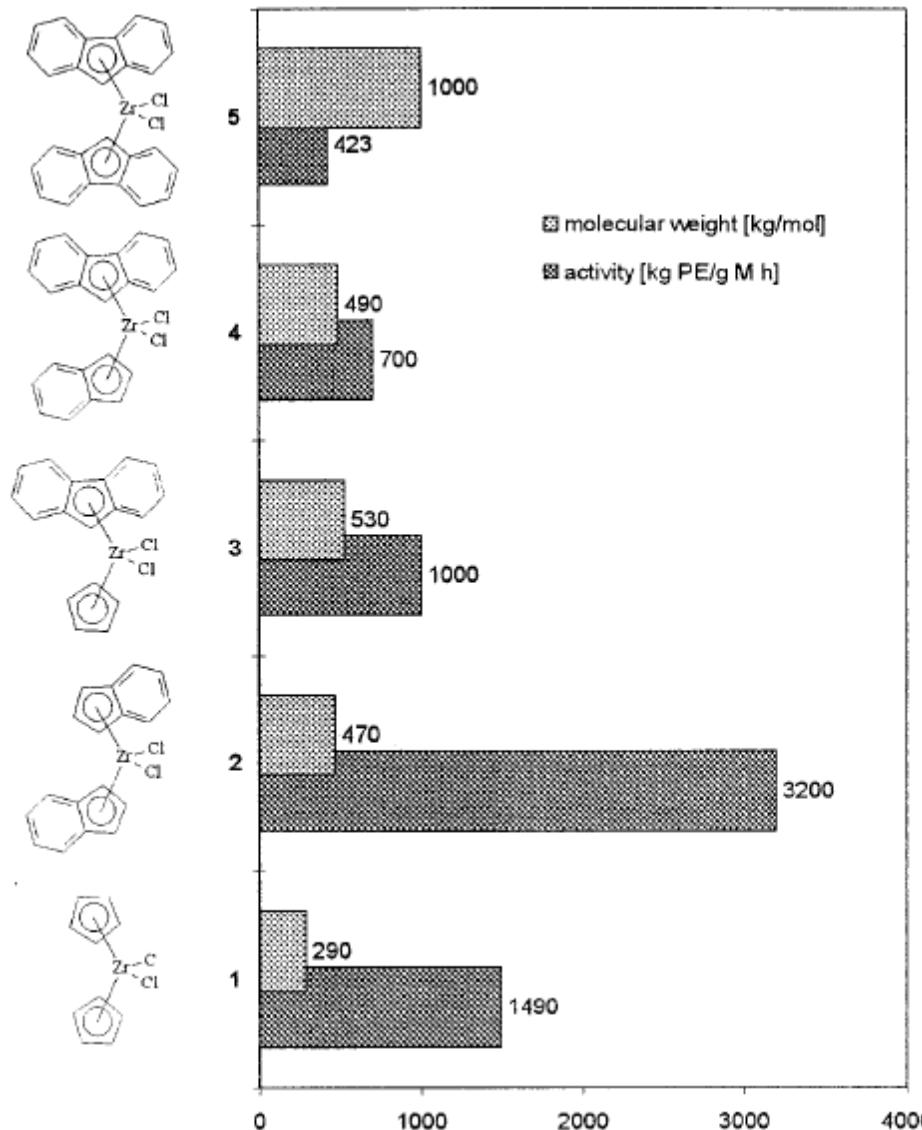

Reaction conditions: $T = 90 \text{ }^{\circ}\text{C}$, $P_{\text{ethylene}} = 8 \text{ bar}$,
 $\boxed{[\text{Al}]/[\text{Zr}] = 10\,000}$,
solvent = toluene

Productivity: $5 \cdot 10^6 \text{ g PE/g Zr} \cdot \text{h} \cdot \text{bar}$
 $M_n = 122\,000$

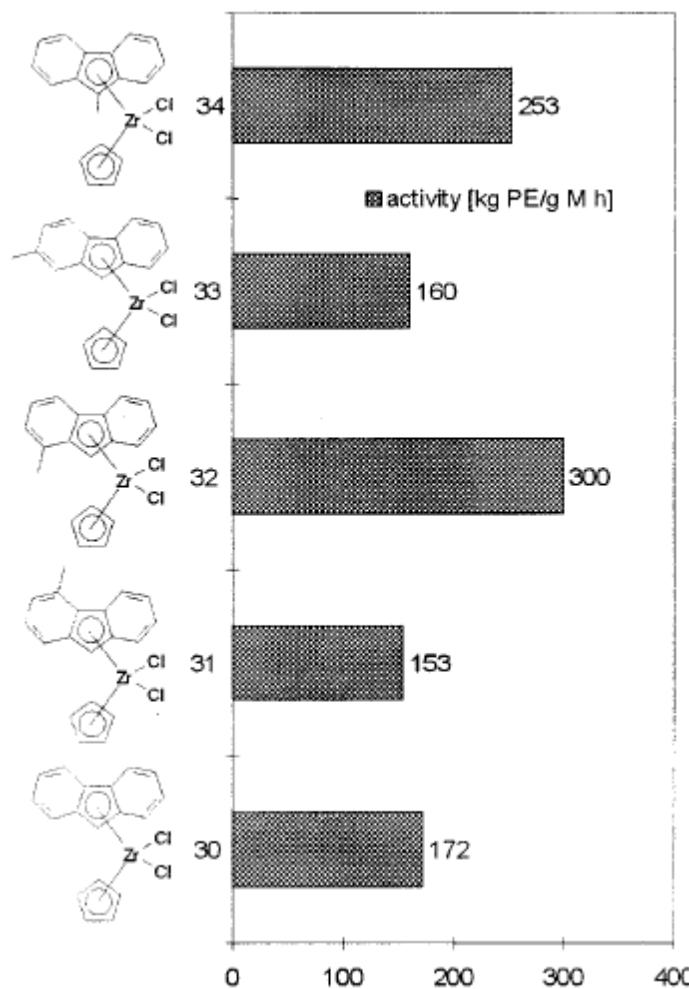

T. Masuda, *Catalysis in Precision Polymerisation* 1997, Ed. Wiley, pg. 18.

Ethylene polymerization: Effect of the aromatic ring

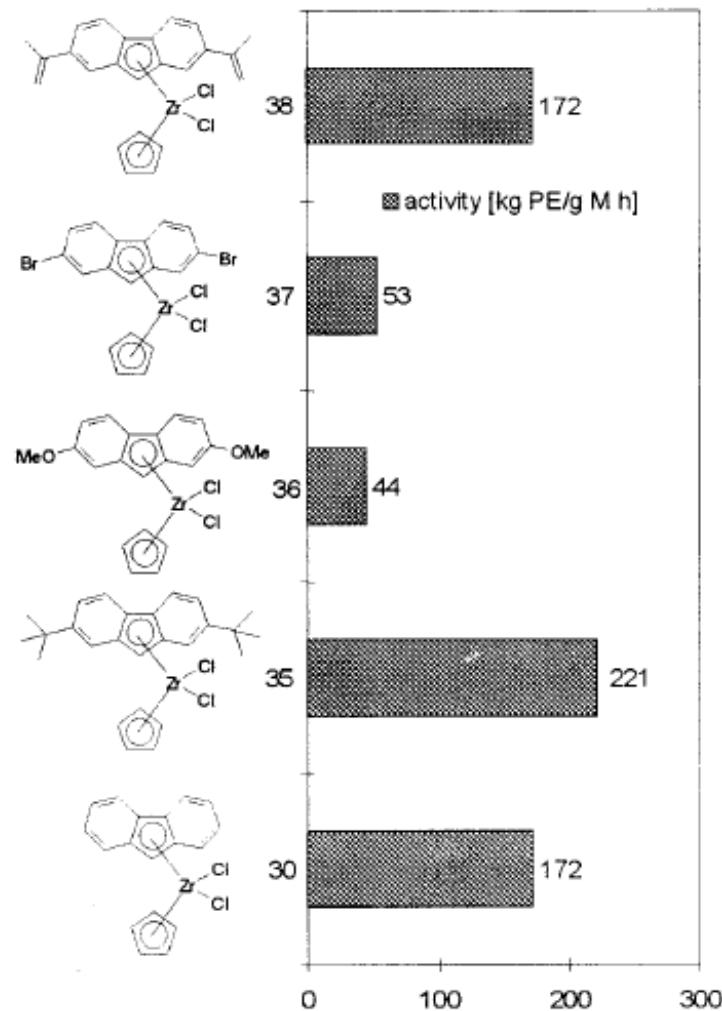

Reaction conditions: T = 60 °C; solvent: *n*-pentane; P_{ethylene} = 10.0 bar; Cat. Prec. **1, 2, 4** [Al]/[Zr] = 1000; Cat. Prec. **3, 5** [Al]/[Zr] = 2500.

Ethylene polymerization: Effect of substituent position

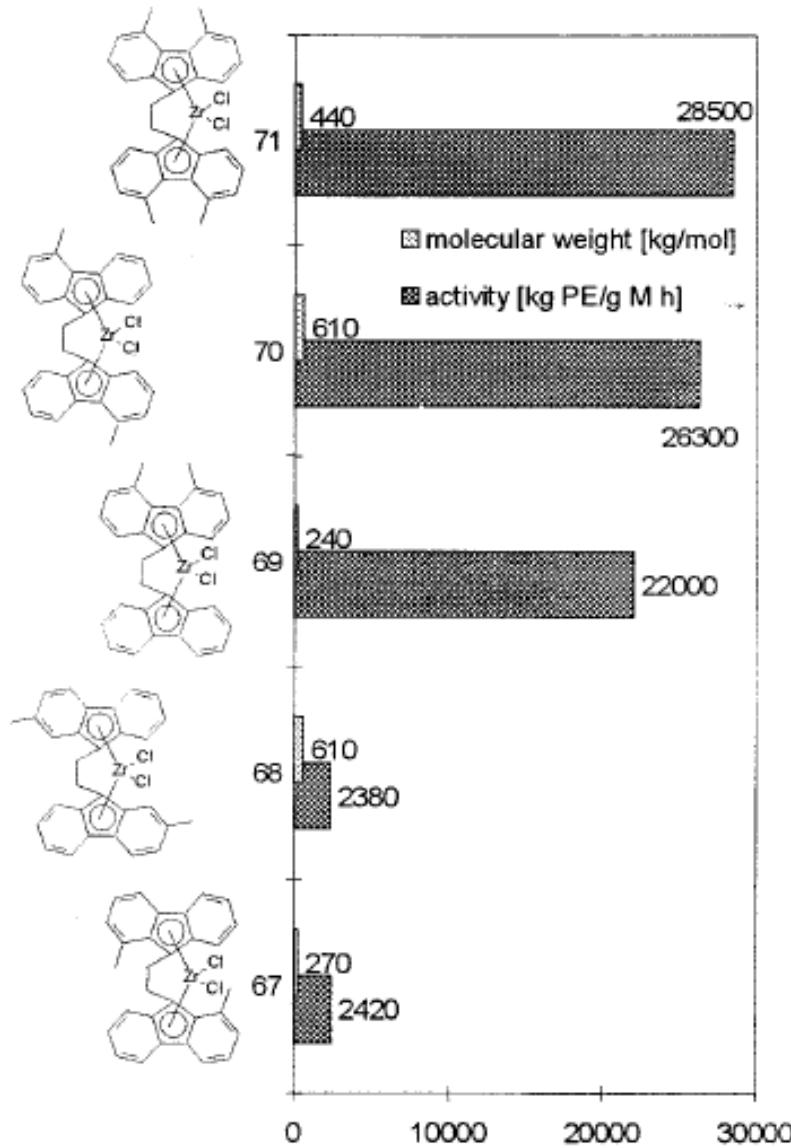

substituent nature

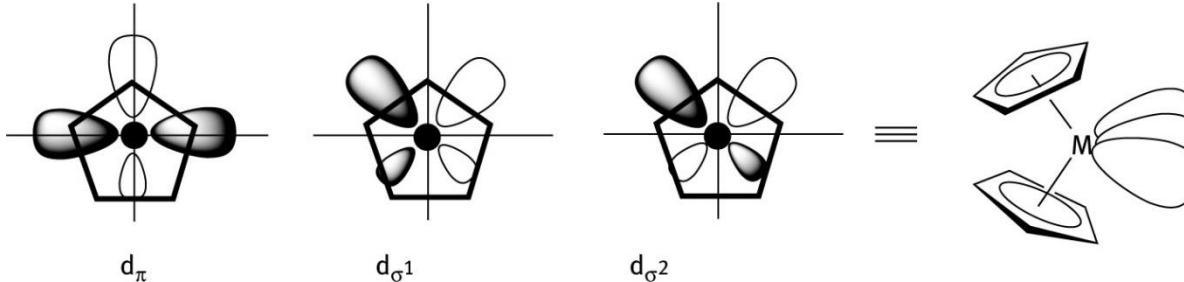

Reaction conditions: T = 10 °C; solvent: *n*-pentane; P_{ethylene} = 10.0 bar;
[Al]/[Zr] = 1000.

Ethylene polymerization: Effect of substituent position in *ansa*-metallocenes

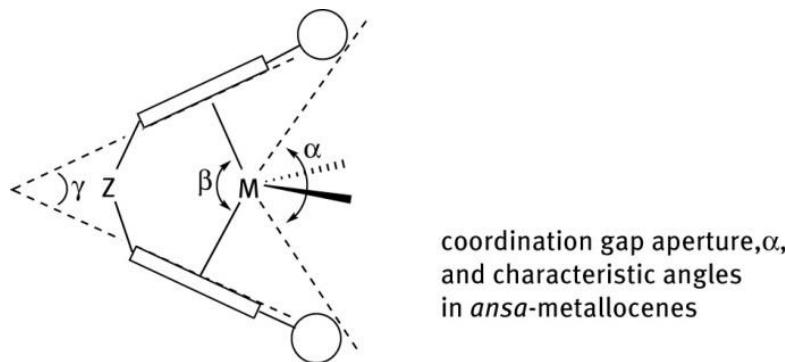

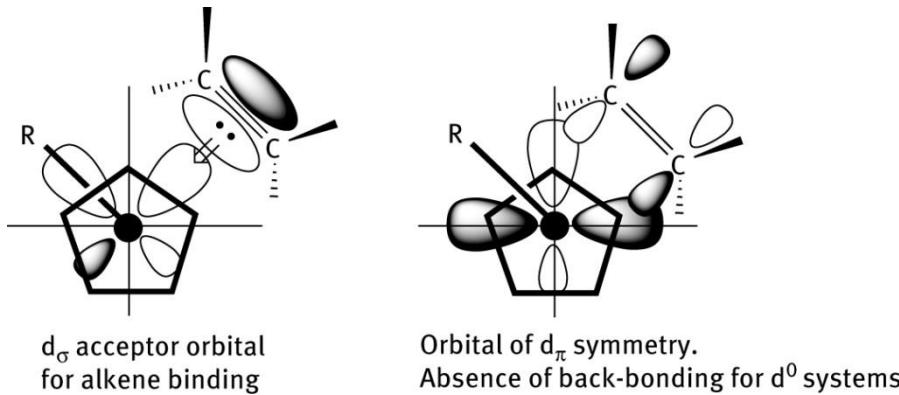

Reaction conditions:
 $T = 60^\circ\text{C}$;
solvent: *n*-pentane;
 $P_{\text{ethylene}} = 10.0 \text{ bar}$;
[Al]/[Zr] = 20000.

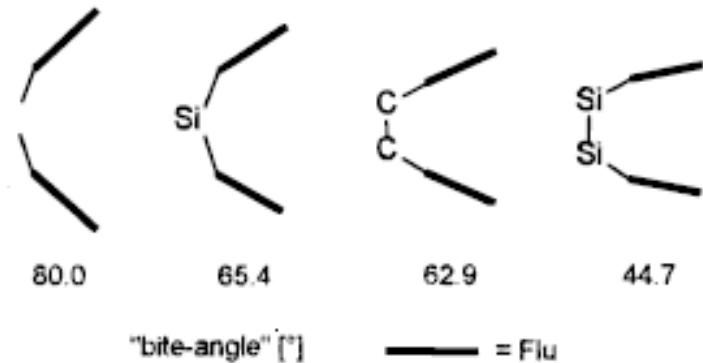

Frontier orbitals in $[\text{Zr}(\text{Cp})_2]^{2+}$

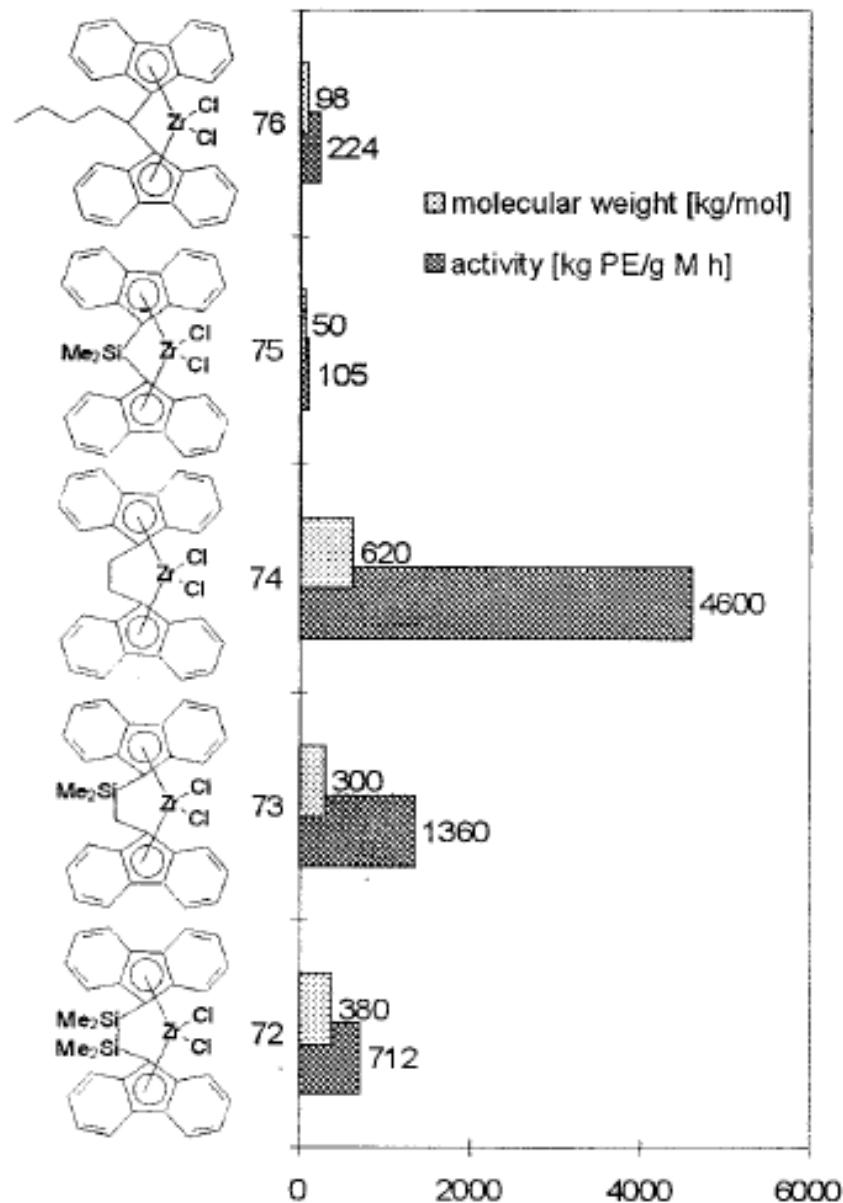

Frontier orbitals in $[\text{Zr}(\text{Cp})_2\text{R}]^+$

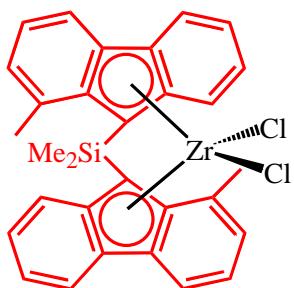

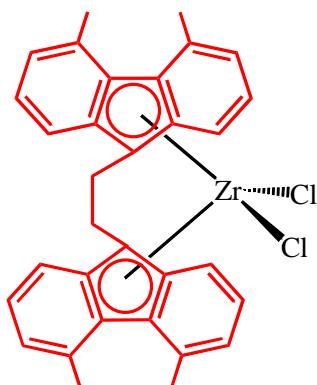

Ethylene polymerization: Effect of ligand bite angle

Reaction conditions: T = 60 °C;
solvent: *n*-pentane; P_{ethylene} = 10.0 bar;
[Al]/[Zr] = 20000.

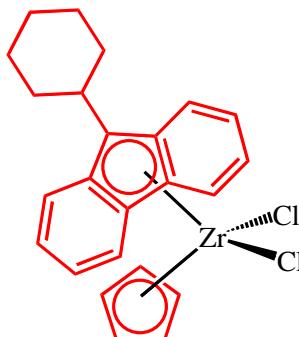

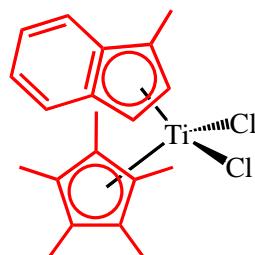

The “TOP FOUR” Catalysts¹

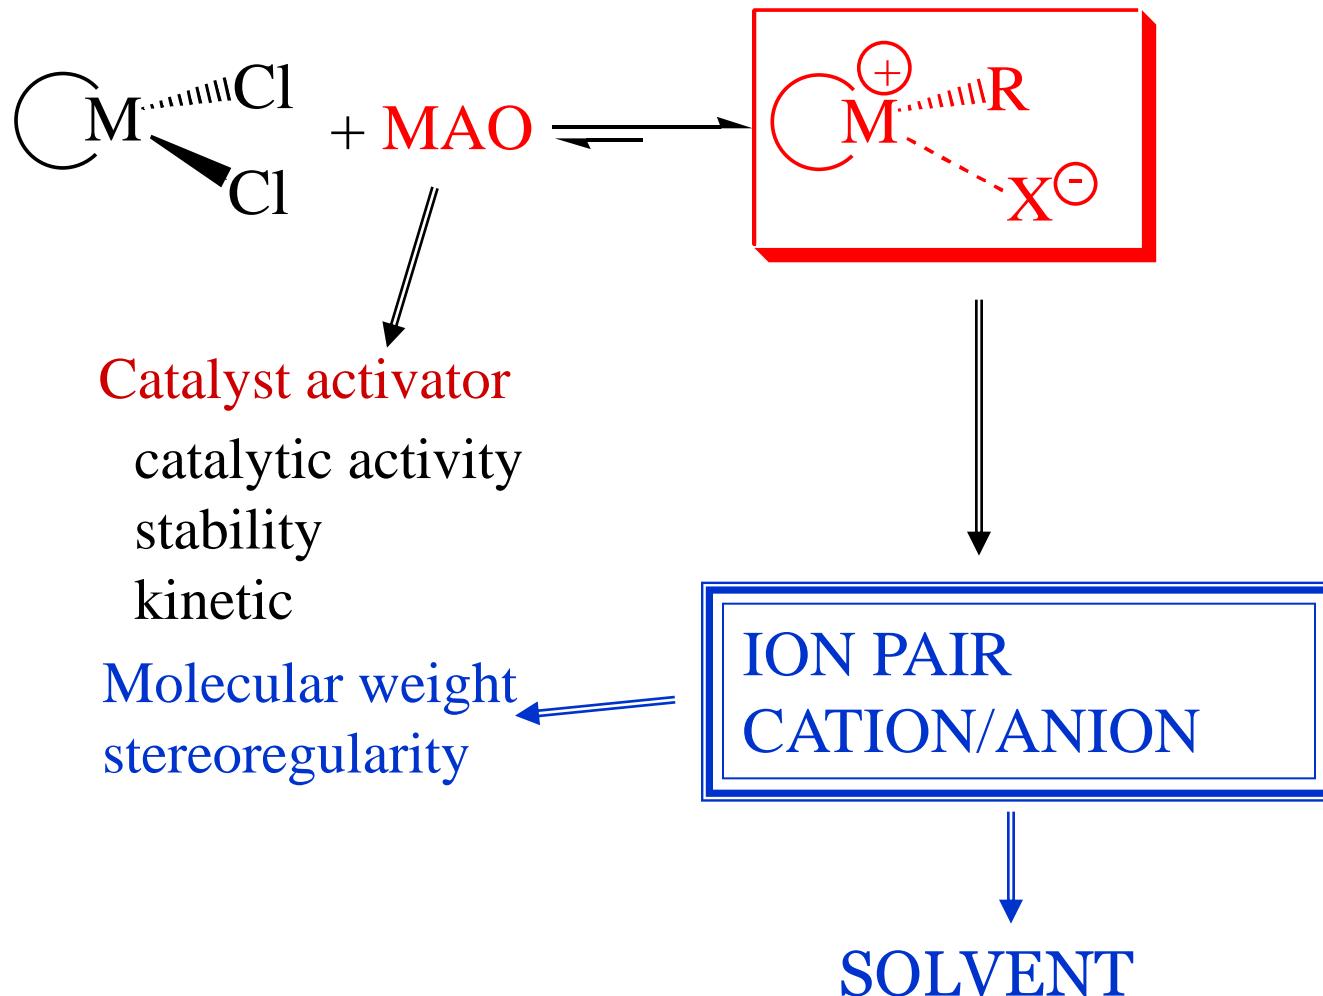

$$[\text{Al}]/[\text{Zr}] = 20\,000$$

High molecular weight polyethylene

Accepted mechanism for the growth of polymer chain

Overall mechanism for catalyst activation and growth of polymer chain

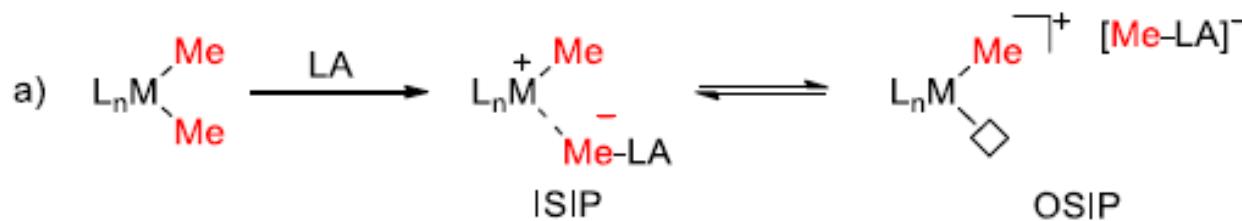

Activation process: a comparison

MAO as activation agent

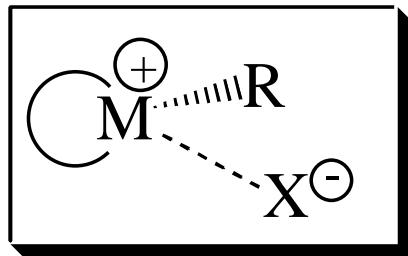

Boranes as activation agents

Ion pair effect in polymerization reactions

- ❖ the catalytic system is a **two component** system: the **precatalyst** that is a **metallocene organometallic species** and the **catalyst activator** that is an **organometallic compound based on Al or on B**;
- ❖ the two components react each other leading to the **ion pair**:

It is the catalyst ***resting state***.

ISIP

Effect of the anion in polymerization reactions

Catalytic activity increases on decreasing the coordination capability of the anion.

When $\text{X}^- = \text{MeB}(\text{C}_6\text{F}_5)_3^-$

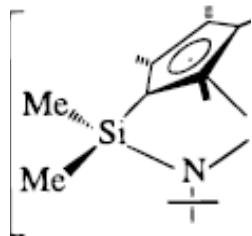

when $\text{M} = \text{Zr}$: **inactive system**

when $\text{M} = \text{Ti}$: **slightly active system**

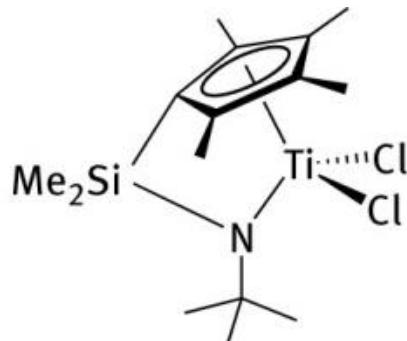

When $\text{X}^- = \text{MePBB}^-$

when $\text{M} = \text{Zr}$: **active system**: $v = 10^5$

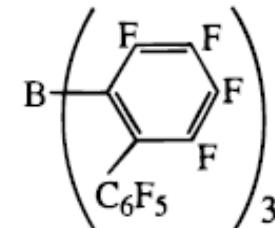

when $\text{M} = \text{Ti}$: the **system is 70 times more active than the previous one**

CGC

Cp-amido "constrained geometry" complex

PBB

Drawbacks of metallocene catalysts¹

- ❖ They are easily **poisoned** by compounds containing heteroatoms;
- ❖ they are **very expensive** and are synthesized according to a multistep process;
- ❖ the use of **MAO**:
 - i. in **large excess** with respect to the metal;
 - ii. it has a relatively **high cost**, due to the high cost of AlMe_3 ;
 - iii. **high residual** content of alumina in the final product;
 - iv. **intrinsic danger** due to the use of extremely pyrophoric AlMe_3 .
