Random numbers with non uniform distributions

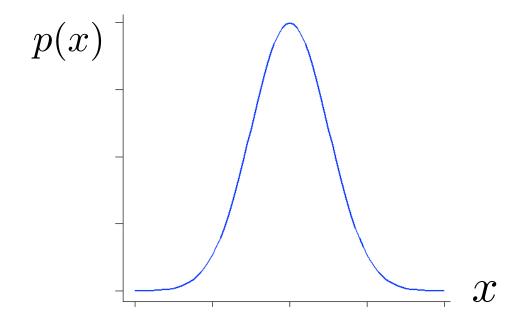

M. Peressi - UniTS - Laurea Magistrale in Physics Laboratory of Computational Physics - week III

last lecture:

generation of real (pseudo)random numbers with uniform distribution in [0;1[

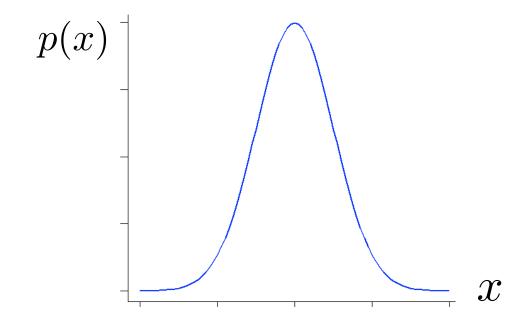

Random numbers with non uniform distributions:

How can we generate random numbers with a given distribution p(x)?

Random numbers with non uniform distributions:

- 1) inverse transformation method (general)
- 2) rejection method (even more general)
- 3) some "ad hoc" methods: the Box-Muller algorithm for the gaussian distribution; the central limit theorem

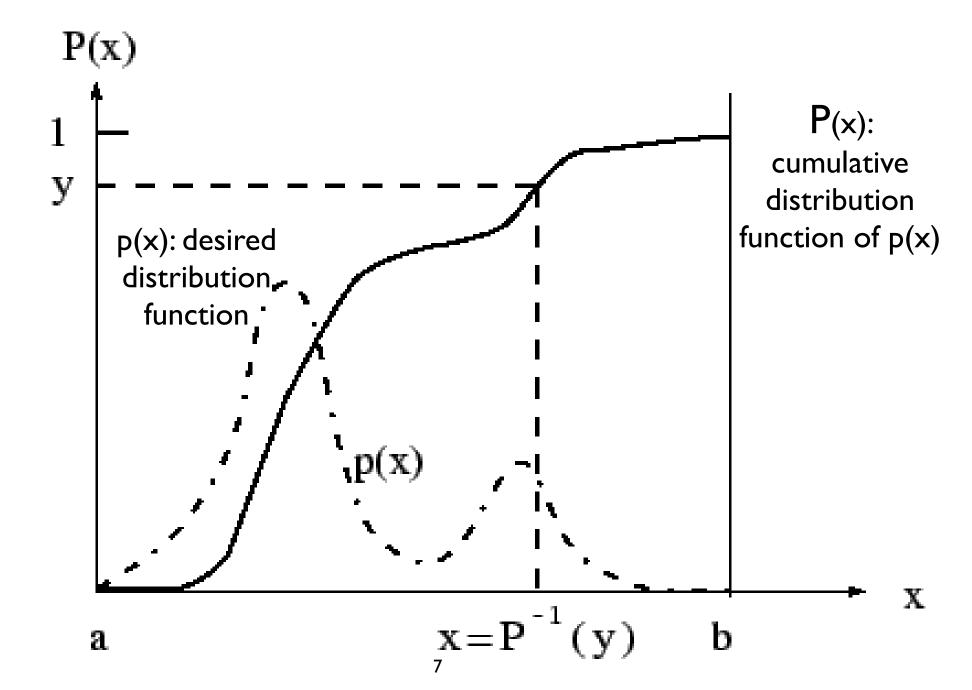

I) inverse transformation method (general)

Problem: Generate sample of a random variable (or *variate*) X with a given distribution p.

Solution: 2-step process

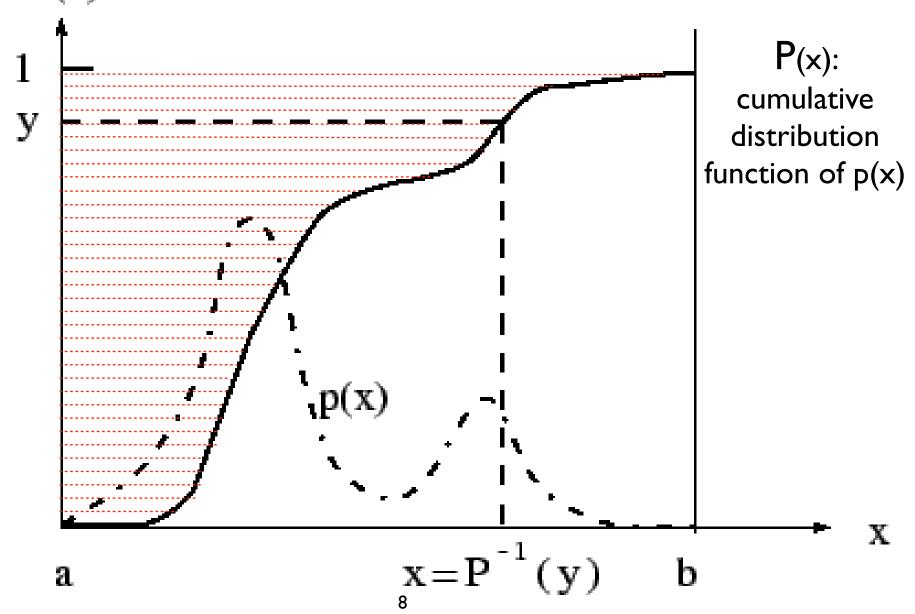

- ullet Generate a random variate uniformly distributed in [0,1] .. also called a random number
- Use an appropriate transformation to convert the random number to a random variate of the correct distribution

1) inverse transformation method - the idea

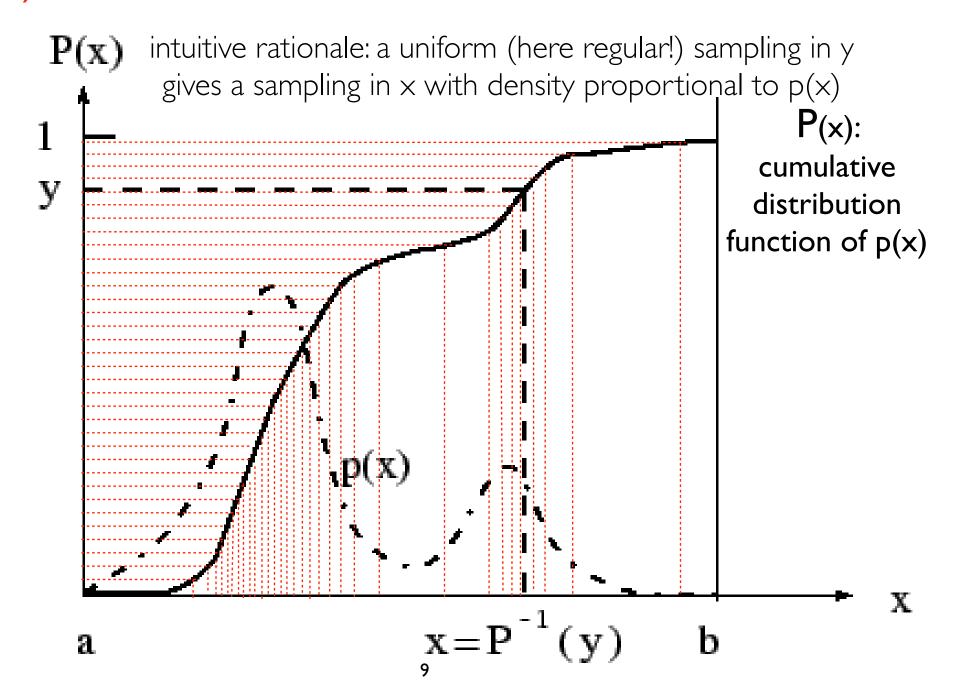

I) inverse transformation method - the idea

 $\mathbf{P}(\mathbf{x})$ intuitive rationale: a uniform (here regular!) sampling in y

1) inverse transformation method - the idea

I) inverse transformation method - algorithm

cumulative distribution function P(x)

$$\int_{-\infty}^{+\infty} p(x)dx = 1$$

Let p(x) be a desired distribution, and $y = P(x) = \int_{-\infty}^{x} p(x')dx'$ the corresponding *cumulative distribution*. Assume that $P^{-1}(y)$ is known.

- Sample y from an equidistribution in the interval (0,1). (i.e., use $p_u(y)$)
- Compute $x = P^{-1}(y)$.

The variable x then has the desired probability density p(x).

$$y = P(x) \Longrightarrow dy = dP(x) \Longrightarrow p_u(y)dy = dP(x) \text{ (since } p_u(y) = 1 \text{ for } 0 \le y \le 1)$$

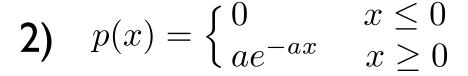

But: $dP(x) = p(x)dx$, therefore $p(x)dx = p_u(y)dy$

I) inverse transformation method - examples

I)
$$p(x) = \begin{cases} \frac{1}{b-a} & a \le x \le b \\ 0 & \text{otherwise} \end{cases}$$

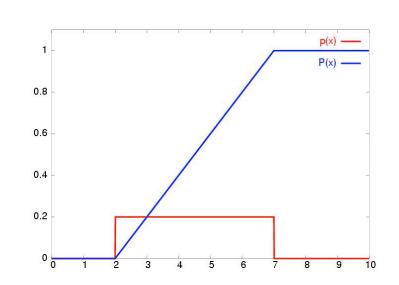

$$y = P(x) = \begin{cases} 0 & x \le a \\ \int_{a}^{x} \frac{1}{b-a} dx' = \frac{x-a}{b-a} & a \le x \le b \\ 1 & x > b \end{cases}$$

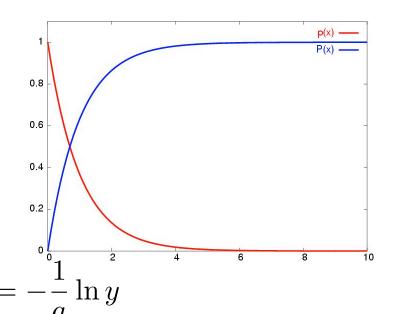

$$x = y(b - a) + a$$

$$y = P(x) = \begin{cases} 0 & x \le 0\\ 1 - e^{-ax} & x \ge 0 \end{cases}$$

$$x = -\frac{1}{a}\ln(1-y)$$
 or (same distribution!) $x = -\frac{1}{a}\ln y$

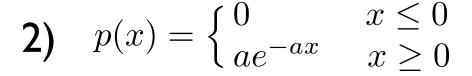

I) inverse transformation method - examples

1)
$$p(x) = \begin{cases} \frac{1}{b-a} & a \le x \le b \\ 0 & \text{otherwise} \end{cases}$$

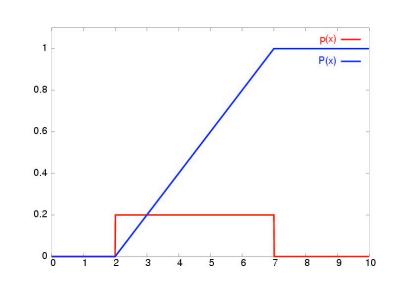

$$y = P(x) = \begin{cases} 0 & x \le a \\ \int_{a}^{x} \frac{1}{b-a} dx' = \frac{x-a}{b-a} & a \le x \le b \\ 1 & x > b \end{cases}$$

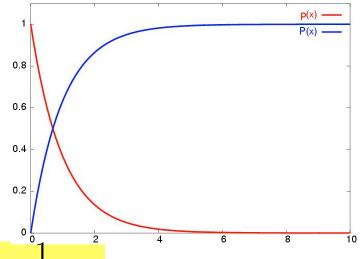

$$x = y(b - a) + a$$

$$y = P(x) = \begin{cases} 0 & x \le 0 \\ 1 - e^{-ax} & x > 0 \end{cases}$$

$$x = -\frac{1}{a}\ln(1-y)$$
 or (same distribution!) $x = -\frac{1}{a}\ln y$

Codes available on moodle

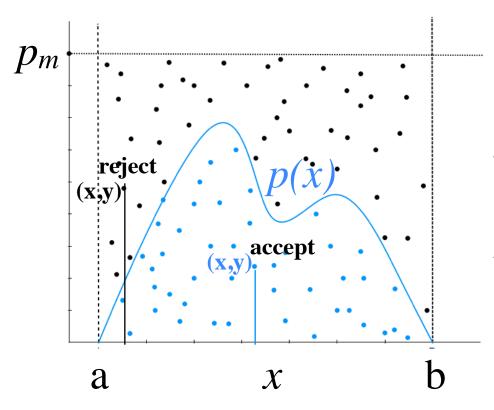

expdev.f90

```
subroutine expdev(x)
   REAL, intent (out) :: x
   REAL :: r
   do
                               r is generated in [0, 1];
     call random number(r) but r=0 has to be discarded;
                               if r=0, generate another random number;
     if(r > 0) exit
                               if not, exit from the unbounded loop
   end do
                               and calculate its log
  x = -log(r)
 END subroutine expdev
```

2) rejection method (general)

Let [a, b] be the allowed range of values of the variate x, and p_m the maximum of the distribution p(x).

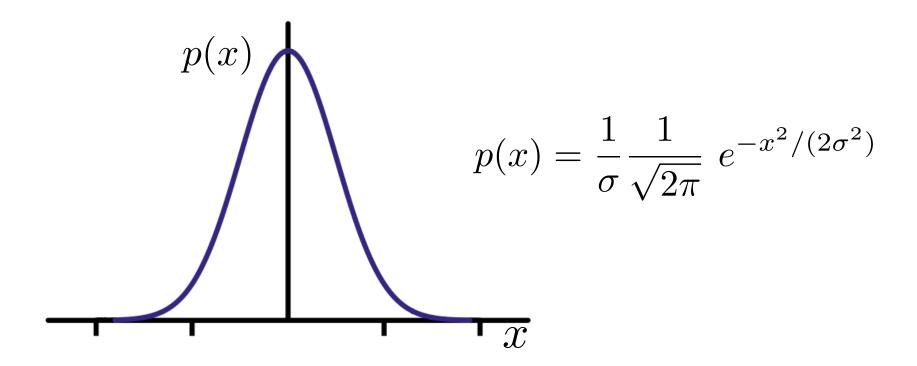

- 1. Sample a pair of equidistributed random numbers, $x \in [a, b]$ and $y \in [0, p_m]$.
- 2. If $y \leq p(x)$, accept x as the next random number, otherwise return to step 1.

Due to Von Newmann (1947). Applicable to almost all distributions. Can be inefficient if the area of the rectangle $[a,b] \otimes [0,p_m]$ is large compared to the area below the curve p(x)

[no exercises on that]

3) gaussian distribution

How to produce numbers with gaussian distribution?

- Inverse transformation method: impossible

The cumulative distribution function P(x) cannot be analytically calculated!

- Rejection method: inefficient

$$p(x) = \frac{1}{\sigma} \frac{1}{\sqrt{2\pi}} e^{-x^2/(2\sigma^2)}$$

Hint: consider the distribution in 2D instead of ID (here $\sigma = I$):

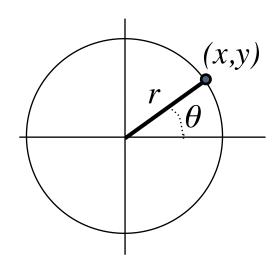

$$p(x)p(y)dxdy = (2\pi)^{-1} e^{-(x^2+y^2)/2} dxdy$$

$$p(x) = \frac{1}{\sigma} \frac{1}{\sqrt{2\pi}} e^{-x^2/(2\sigma^2)}$$

Hint: consider the distribution in 2D instead of ID (here $\sigma = I$):

$$p(x)p(y)dxdy = (2\pi)^{-1} e^{-(x^2+y^2)/2} dxdy$$

Use polar coordinates: $r=\sqrt{x^2+y^2}$, $\theta=\arctan{(y/x)}$; def.: $\rho\equiv r^2/2$

$$p(x) = \frac{1}{\sigma} \frac{1}{\sqrt{2\pi}} e^{-x^2/(2\sigma^2)}$$

Hint: consider the distribution in 2D instead of ID (here $\sigma = I$):

$$p(x)p(y)dxdy = (2\pi)^{-1} e^{-(x^2+y^2)/2} dxdy$$

Use polar coordinates: $r=\sqrt{x^2+y^2}$, $\theta=\arctan{(y/x)}$; def.: $\rho\equiv r^2/2$ $\to dxdy=r\ dr\ d\theta=d\rho\ d\theta$

and therefore:

$$p(x)p(y) dx dy = p(\rho, \theta) d\rho d\theta = (2\pi)^{-1} e^{-\rho} d\rho d\theta$$

$$p(x) = \frac{1}{\sigma} \frac{1}{\sqrt{2\pi}} e^{-x^2/(2\sigma^2)}$$

Hint: consider the distribution in 2D instead of ID (here $\sigma = I$):

$$p(x)p(y)dxdy = (2\pi)^{-1} e^{-(x^2+y^2)/2} dxdy$$

Use polar coordinates: $r=\sqrt{x^2+y^2}$, $\theta=\arctan{(y/x)}$; def.: $\rho\equiv r^2/2$ $\rightarrow dxdy = r dr d\theta = d\rho d\theta$

and therefore:

$$p(x)p(y) dx dy = p(\rho, \theta) d\rho d\theta = (2\pi)^{-1} e^{-\rho} d\rho d\theta$$

$$\begin{cases} \rho \text{ exponentially distributed} \\ \theta \text{ uniformly distributed in}[0, 2\pi] \end{cases} \rightarrow \begin{cases} x = r \cos \theta = \sqrt{2\rho} \cos \theta \\ y = r \sin \theta = \sqrt{2\rho} \sin \theta \\ x, y \text{ have gaussian distribution with } \langle x \rangle = \langle y \rangle = 0 \text{ and } \sigma = 1 \end{cases}$$

If
$$\begin{cases} \rho \text{ exponentially distributed} \\ \theta \text{ uniformly distributed in}[0,2\pi] \end{cases} \rightarrow \begin{cases} x = r\cos\theta = \sqrt{2\rho}\cos\theta \\ y = r\sin\theta = \sqrt{2\rho}\sin\theta \\ x,y \text{ have gaussian distribution with } \langle x \rangle = \langle y \rangle = 0 \text{ and } \sigma = 1 \end{cases}$$

Recipe #I (BASIC FORM):

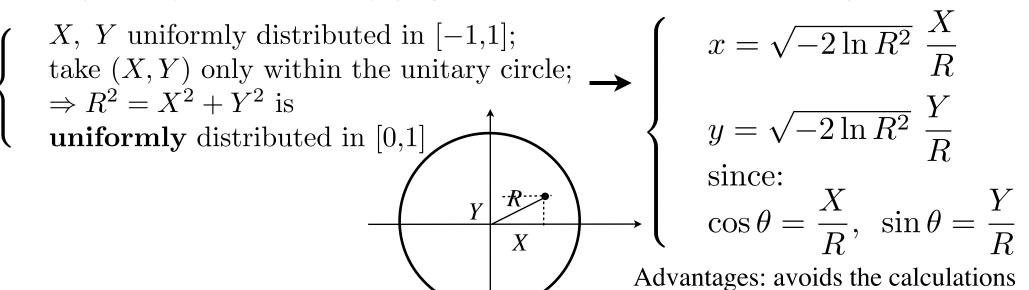

$$\begin{cases} X, Y \ unif. \ distrib. \ in \ [0,1[\\ \rho = -\ln(X) \ distributed \ with \ p(\rho) = e^{-\rho} \\ \theta = 2\pi Y \ distributed \ with \ (2\pi)^{-1}p_u \end{cases} \begin{cases} x = r\cos\theta = \sqrt{-2\ln X}\cos(2\pi Y) \\ y = r\sin\theta = \sqrt{-2\ln X}\sin(2\pi Y) \end{cases}$$

NOTE:

x, y are normally distributed and statistically independent. Gaussian variates with given variances σ_x , σ_y are obtained by multiplying x and y by σ_x and σ_y respectively

If
$$\begin{cases} \rho \text{ exponentially distributed} \\ \theta \text{ uniformly distributed in}[0, 2\pi] \end{cases} \rightarrow \begin{cases} x = r \cos \theta = \sqrt{2\rho} \cos \theta \\ y = r \sin \theta = \sqrt{2\rho} \sin \theta \\ x, y \text{ have gaussian distribution} \\ \text{with } \langle x \rangle = \langle y \rangle = 0 \text{ and } \sigma = 1 \end{cases}$$

Recipe #2 (POLAR FORM) (implemented in boxmuller.f90):

of sin and cos functions

2 examples of optimization!

$$x = \sqrt{-2 \ln R^2} \; \frac{X}{R} = X \sqrt{-2 \ln R^2/R^2}$$
 (thus avoiding the calculation of another $\sqrt{}$ to calculate R separately)

A look at the gasdev.c code

```
#include <math.h>
float gasdev(long *idum)
    float ran1(long *idum);
                                Every two calls
    static int iset=0;
    static double gset;
                                uses the random number
    double fac, rsq, v1, v2;
                                already generated in the previous call
    if (iset == 0) {
        do {
                                         2 examples of optimization!
             v1=2.0*ran1(idum)-1.0;
             v2=2.0*ran1(idum)-1.0;
             rsq=v1*v1+v2*v2;
        } while (rsq >= 1.0 || rsq == 0.0);
        fac=sqrt(-2.0*log(rsq)/rsq); \longrightarrow since: x = \sqrt{-2 \ln R^2} \frac{X}{R} = X \sqrt{-2 \ln R^2/R^2}
        gset=v1*fac;
                                           (thus avoiding the calculation of
        iset=1;
        return (float)(v2*fac);
                                           another \sqrt{} to calculate R separately)
    } else {
        iset=0;
        return (float)gset;
```

Consider a continuous random variable x with probability density f(x).

characterized by
$$\langle x^m \rangle = \int x^m f(x) dx$$
 and $\sigma_x^2 = \langle x^2 \rangle - \langle x \rangle^2$.

Consider y s.t. y_n corresponding to the average of n values of x:

$$y = y_n = \frac{1}{n}(x_1 + x_2 + \dots + x_n)$$

Suppose that we make many measurements of y. The variable y is distributed according to a probability density $P(y) \neq f(x)$

quantities of interest are the mean $\langle y \rangle$, the variance $\sigma_y^2 = \langle y^2 \rangle - \langle y \rangle^2$, and P(y) itself.

The random variable:

$$y = y_n = \frac{1}{n}(x_1 + x_2 + \dots + x_n)$$

is distributed according to:

P(y): gaussian distribution

with:

$$\langle y \rangle = \langle x \rangle$$
 $\sigma_y \approx \sigma_x / \sqrt{n}$

(Therefore, the sample mean of a random sample is better than a single observation)

provided $\langle x \rangle$ and $\langle x^2 \rangle$ exist (finite) and n is large!

Analogously, is instead of considering the new random variable as the **average** we consider just the **sum:**

$$y = x_1 + x_2 + \dots + x_n$$

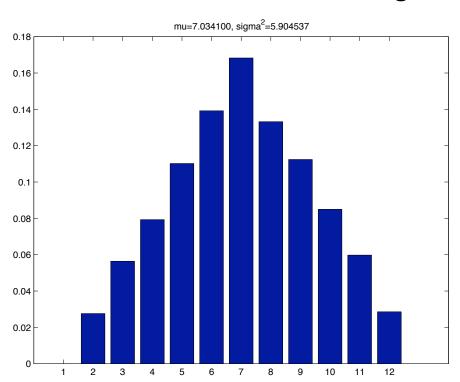

it also has a gaussian distribution but with:

$$\langle y \rangle = n \langle x \rangle$$
 and $\sigma_y \approx \sqrt{n} \sigma_x$

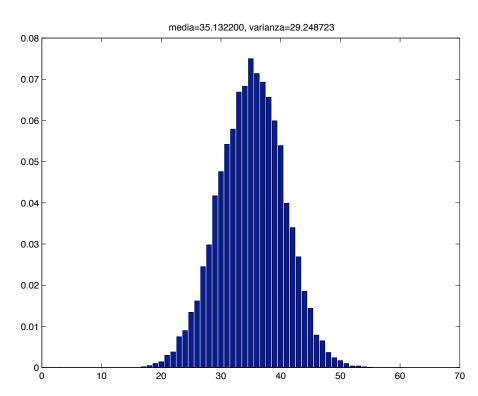

provided $\langle x \rangle$ and $\langle x^2 \rangle$ exist (finite) and n is large!

Note: large enough n needed to obtain the gaussian distribution. Suppose that f(x) is uniform: e.g., playing dice:

n=2 not enough

n=100 OK

The previous example was for UNIFORM distribution (dice) but the central limit theorem work also with random deviates x with NON UNIFORM distribution; e.g. with exponential distribution:

$$f(x) = \begin{cases} e^{-x}, & \text{if } x \ge 0 \\ 0, if & x < 0 \end{cases}.$$

the central limit theorem

...but sometimes it doesn't work:

Cauchy-Lorentz

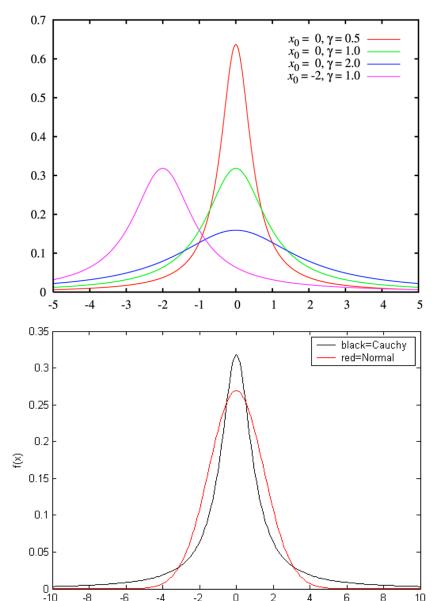

probability density function

$$f(x; x_0, \gamma) = \frac{1}{\pi \gamma \left[1 + \left(\frac{x - x_0}{\gamma} \right)^2 \right]}$$
$$= \frac{1}{\pi} \left[\frac{\gamma}{(x - x_0)^2 + \gamma^2} \right]$$

The Cauchy-Lorentz distribution is an example of "fat-tailed" distribution.

Fat-tailed distributions decay to infinity slower than exponentially.

For instance, they can decay with a power law: $f(x) \sim x^{-(1+\alpha)}$ as $x \to +\infty$ In some cases the expression "fat-tailed" indicates distributions where $0 < \alpha < 2$.

the central limit theorem

...but sometimes it doesn't work:

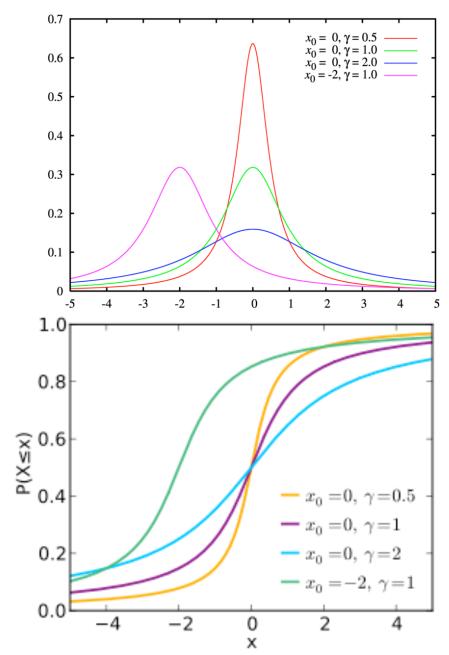

Cauchy-Lorentz

probability density function

$$f(x; x_0, \gamma) = \frac{1}{\pi \gamma \left[1 + \left(\frac{x - x_0}{\gamma}\right)^2\right]}$$
$$= \frac{1}{\pi} \left[\frac{\gamma}{(x - x_0)^2 + \gamma^2}\right]$$

Cumulative

Cumulative distribution:
$$\frac{1}{\pi}\arctan\left(\frac{x-x_0}{\gamma}\right) + \frac{1}{2}$$

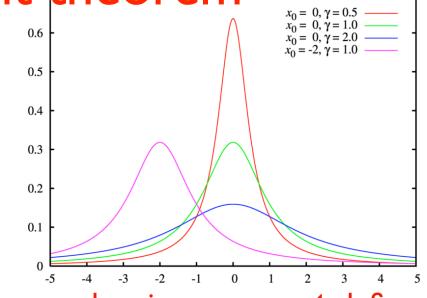

the central limit, theorem

...but sometimes it doesn't work:

Cauchy-Lorentz

probability density function

$$f(x; x_0, \gamma) = \frac{1}{\pi \gamma \left[1 + \left(\frac{x - x_0}{\gamma} \right)^2 \right]}$$
$$= \frac{1}{\pi} \left[\frac{\gamma}{(x - x_0)^2 + \gamma^2} \right]$$

Mean and variance are **not** defined

The mean:
$$\int_{-\infty}^{\infty} x f(x) \, dx \qquad \text{which can be rewritten as: } \int_{0}^{\infty} x f(x) \, dx - \int_{-\infty}^{0} |x| f(x) \, dx$$

is not defined since both terms are infinite; only the Cauchy principal value is defined:

$$\lim_{a \to \infty} \int_{-a}^{a} x f(x) \, dx$$

Without a defined mean, it is impossible to define the variance (but the second moment is defined and it is infinite). Some results in probability theory about expected values, such as the law of large numbers, do not work in such cases.

Also, the mean of a set of random variates drawn from a Cauchy distribution is no better than a single observation, because the chance of including extreme values is high.

Student's t-distribution

(più generale)

$$f(t_n) = rac{\Gamma\left(rac{n+1}{2}
ight)}{\sqrt{\pi n}\Gamma\left(rac{n}{2}
ight)} \cdot \left(1 + rac{t^2}{n}
ight)^{-rac{n+1}{2}}$$

0.40 0.35 0.300.25 [∞] 0.20 0.15 0.10 0.05 0.00 $\lim_{n \to \infty} \left(1 + \frac{t^2}{n} \right)^{-\frac{n+1}{2}} \sim \frac{1}{t^{-(n+1)}}$ Notiamo che il limite di questa successione di funzioni per $n \to \infty$ è

Varianza $\frac{n}{n-2}$ se n>2

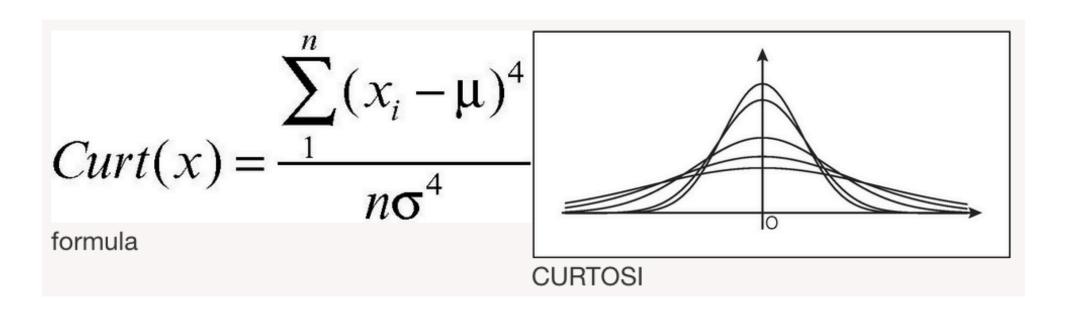

infinita altrimenti

 $\lim_{n o\infty}f(t_n)=rac{1}{\sqrt{\pi}}\lim_{n o\infty}rac{\Gamma\left(rac{n+1}{2}
ight)}{\sqrt{n}\Gamma\left(rac{n}{2}
ight)}\lim_{n o\infty}\left(1+rac{t^2}{n}
ight)^{-rac{n+1}{2}}=rac{1}{\sqrt{2\pi}}e^{-rac{t^2}{2}}.$

Sapendo che il primo limite ha come risultato $\frac{1}{\sqrt{2}}$ e il secondo tende a $e^{-\frac{t^2}{2}}$.

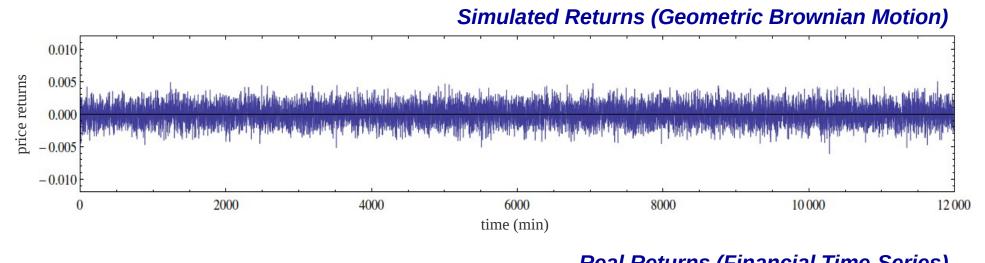

In pratica, prendendo una popolazione di numerosità N molto grande, la variabile aleatoria t tende ad essere una normale standard.

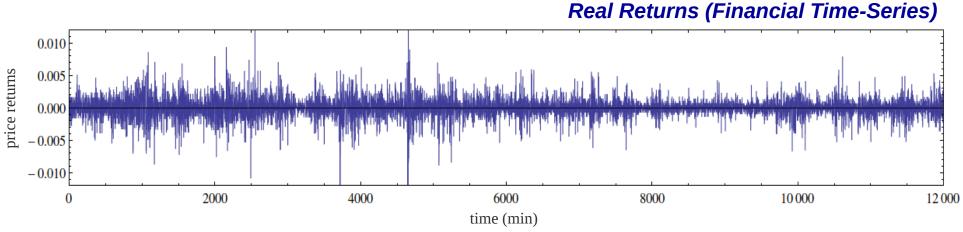

Curtosi (dal greco *kurtós*, gobba) in statistica, termine che indica quanto una distribuzione di dati si allontani da una curva normale standardizzata (cioè se è, rispetto a questa, per la quale l'indice è 0, più "schiacciata" o meno "schiacciata"). L'*indice di curtosi* per una distribuzione discreta *X* di *n* elementi è dato da:

... a short digression ...

list of EXERCISES; more on fortran90, fit, gnuplot...

LIST OF EXERCISES III week

Random numbers with non uniform distributions

- I) exponential distribution generated with Inverse Transformation Method
- 2) another distribution generated with ad-hoc algorithms (compare!), including Inverse Transformation Method
- 3) gaussian distribution generated with Box-Muller algorithm
- 4) gaussian distribution generated with the central limit theorem
- 5) other random distributions (different algorithms, subroutines from the web...). [optional]

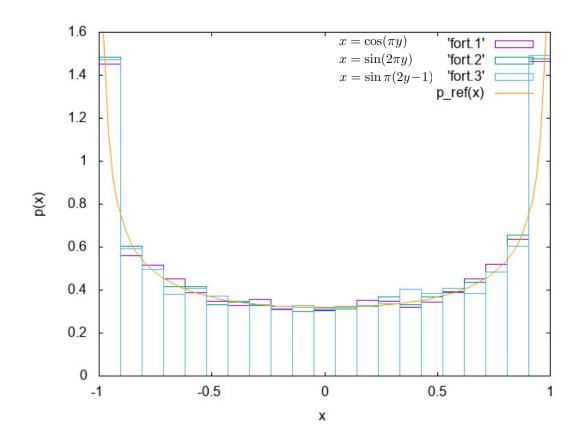

To do: implementation of the algorithms (or understanding...), histogram, fit...

Making histograms: use int() or similar intrinsic functions?

e.g. Ex. 2:

Suppose you want to generate a random variate x in (-1,1) with distribution

$$p(x) = \frac{1}{\pi} (1 - x^2)^{-1/2}.$$

$$y = P(x) = \int_{-1}^{x} \frac{1}{\pi} (1 - x^2)^{-1/2} dx$$
$$= \frac{1}{\pi} \arcsin(x) \Big|_{-1}^{x} = \frac{1}{\pi} \arcsin(x) + \frac{1}{2}$$

and invert...

Here: different histograms, from distributions generated with different algorithms

=> how to do these histograms?

Making histograms: use int() or similar intrinsic functions?

AINT(A[,KIND])

- · Real elemental function
- \cdot Returns A truncated to a whole number. AINT(A) is the largest integer which is smaller than |A|, with the sign of A. For example, AINT(3.7) is 3.0, and AINT(-3.7) is -3.0.
- · Argument A is Real; optional argument KIND is Integer

ANINT(A[,KIND])

- · Real elemental function
- Returns the nearest whole number to A. For example, ANINT(3.7) is 4.0, and AINT(-3.7) is -4.0.
- · Argument A is Real; optional argument KIND is Integer

FLOOR(A,KIND)

- · Integer elemental function
- · Returns the largest integer \leq A. For example, FLOOR(3.7) is 3, and FLOOR(-3.7) is -4.
- · Argument A is Real of any kind; optional argument KIND is Integer
- · Argument KIND is only available in Fortran 95

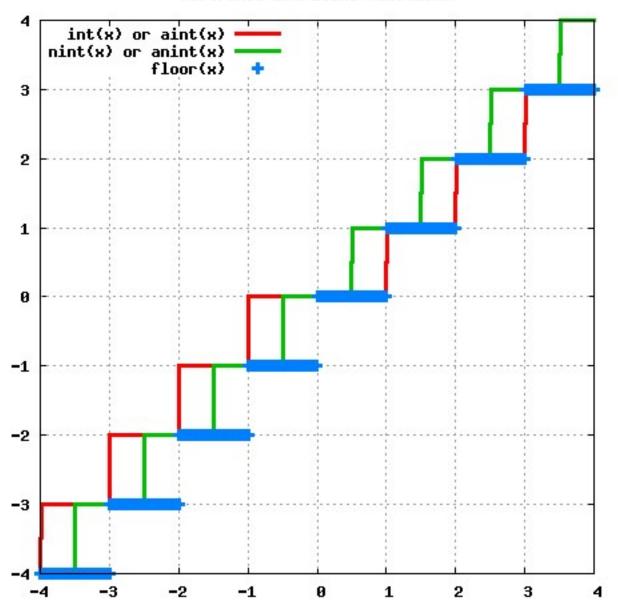

INT(A[,KIND])

- · Integer elemental function
- This function truncates A and converts it into an integer. If A is complex, only the real part is converted. If A is integer, this function changes the kind only.
- · A is numeric; optional argument KIND is Integer.

NINT(A[,KIND])

- · Integer elemental function
- · Returns the nearest integer to the real value A.
- · A is Real

fortran90 intrisinc functions

Example: fit using gnuplot - I

Suppose you want to fit your data (say, 'data.dat') with an exponential function. You have to give: 1) the functional form; 2) the name of the parameters

gnuplot>
$$f(x) = a * exp(-x*b)$$

Then we have to recall these informations together with the data we want to fit: it can be convenient to inizialize the parameters:

gnuplot>
$$a=0.$$
; $b=1.$ (for example)

gnuplot> fit f(x) 'data.dat' via a,b

On the screen you will have something like:

```
a = 1 +/- 8.276e-08 (8.276e-06%)
b = 10 +/- 1.23e-06 (1.23e-05%)
```

correlation matrix of the fit parameters:

a b a 1.000 b 0.671 1.000

It's convenient to plot together the original data and the fit:

Example: fit using gnuplot - II

If you prefer to use linear regression, use logarithmic data in the data file, or directly fit the log of the original data using gnuplot:

gnuplot>
$$f(x) = a + b*x$$

Then we have to recall these informations together with the data we want to fit (in the following example: x=log of the first column; y=log of the second column):

```
gnuplot> fit f(x) 'data.dat' u (log($1)):(log($2)) via a,b
```

Also in this case it will be convenient to plot together the original data and the fit:

```
gnuplot > plot f(x), 'data.dat' u (log($1)):(log($2))
```

In case of needs, we can limit the set of data to fit in a certain range [x_min:x_max]:

A few notes on Fortran

related to the exercises

Intrinsic functions:

LOGARITHM

log returns the natural logarithm

log 10 returns the common (base 10) logarithm

(NOTE: also in **gnuplot**, **log** and **log I 0** are defined with the same meaning)

INTEGER PART

nint(x) and the others, similar but different (see Lect. II) => ex. Il requires histogram for negative and positive data values

Arrays:

possible to label the elements from a negative number or 0: **dimension array(-n:m)** (e.g., useful for making histograms) [default in Fortran: n=1; in c and c++: n=0]

Array dimension:

default : dimension array([1:]n)

but also using other dimensions e.g.: dimension array(-n:m)

Important to **check dimensions** of the array when compiling or during execution!

If not done, it is difficult to interpret error messages (typically: "segmentation fault"), or even possible to obtain unpredictable results!

Default in gfortran:

boundaries not checked; use **compiler option**:

gfortran -fcheck=bounds myprogram.f90

(obsolete but still active alternative: -fbounds-check)

Typing (Unix line command):

man gfortran

you can scroll the manual pages and see the possible compilation options

Some Fortran compiler options

- -fcheck=bounds enables checking for array subscript expressions
- -fbacktrace generate extra information to provide source file traceback at run time Specify that, when a runtime error is encountered or a deadly signal is emitted (segmentation fault, illegal instruction, bus error or floating-point exception), the Fortran runtime library should output a backtrace of the error. This option only has influence for compilation of the Fortran main program.
- -Wall Enables commonly used warning options

. . .

Structure of a main program with one function or subr.

```
program name_program (see: expdev.f90 or boxmuller.f90)
implicit none (*)
<declaration of variables>
<executable statements>

contains

subroutine ... (or function)
...
end subroutine
```

end program

(*) General suggestion for variable declaration:

Use "implicit none" + explicit declaration of variables

See also the use of module

Other programs:

(optional, but useful!)

random.f90 (is a module - generation of rnd with different distributions)
t_random.f90 (main test program)

```
to compile:
```

```
$gfortran random.f90 t_random.f90 (the module first!)
```

```
or in more than one step:
Compile the module with the option -c: this produces .mod and .o (the objects):
gfortran -c random.f90
```

Compile the main program:

gfortran -c t_random.f90

Finally you link all the files *.o and produce the executable:

gfortran -o a.out random.o t_random.o
