Announcements

- Project 1 is due Thursday, April 6th, 11:59 PM PT
- Please follow the announcements at the Teams chat, the class times will have some changes in the coming weeks

272SM: Introduction to Artificial Intelligence

Exercise: Formulating a CSP

Can you phrase the problem of Hamiltonian tour as a CSP (given a network of cities connected by roads, choose an order to visit all cities in a country without repeating any)?

Exercise: Reduction to binary constraints

• Show how a single ternary constraint such as "A+B=C" can be turned into three binary constraints by using an auxiliary variable. You may assume finite domains.

Efficient Solution of CSPs

Iterative Improvement

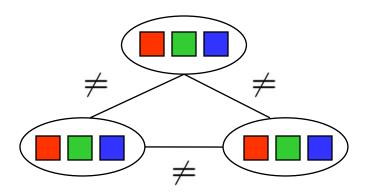

Review: CSPs

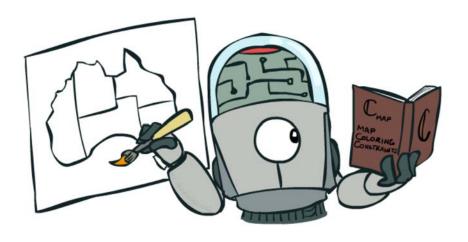

CSPs:

- Variables
- Domains
- Constraints
 - Implicit (provide code to compute)
 - Explicit (provide a list of the legal tuples)
 - Unary / Binary / N-ary

Goals:

- Here: find any solution
- Also: find all, find best, etc.

K-Consistency

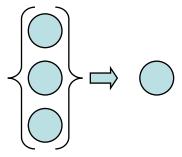

K-Consistency

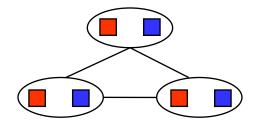

- Increasing degrees of consistency
 - 1-Consistency (Node Consistency): Each single node's domain has a value which meets that node's unary constraints
 - 2-Consistency (Arc Consistency): For each pair of nodes, any consistent assignment to one can be extended to the other
 - K-Consistency: For each k nodes, any consistent assignment to k-1 can be extended to the kth node.

- Higher k more expensive to compute
- (You need to know the k=2 case: arc consistency)

Strong K-Consistency

- Strong k-consistency: also k-1, k-2, ... 1 consistent
- Claim: strong n-consistency means we can solve without backtracking!
- Why?
 - Choose any assignment to any variable
 - Choose a new variable
 - By 2-consistency, there is a choice consistent with the first
 - Choose a new variable
 - By 3-consistency, there is a choice consistent with the first 2
 - **...**
- Lots of middle ground between arc consistency and n-consistency! (e.g. k=3, called path consistency)

Ordering

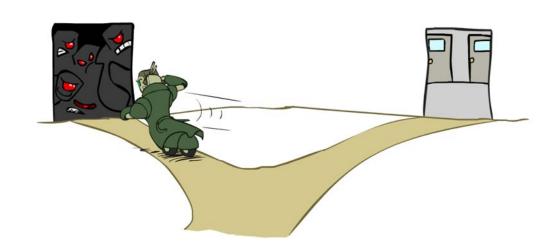

Ordering: Minimum Remaining Values

- Variable Ordering: Minimum remaining values (MRV):
 - Choose the variable with the fewest legal left values in its domain

- Why min rather than max?
- Also called "most constrained variable"
- "Fail-fast" ordering

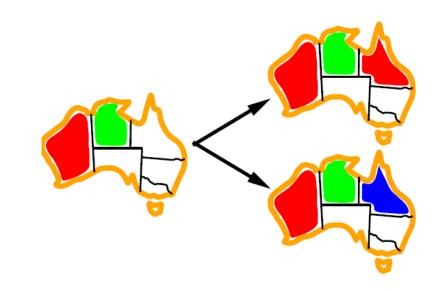

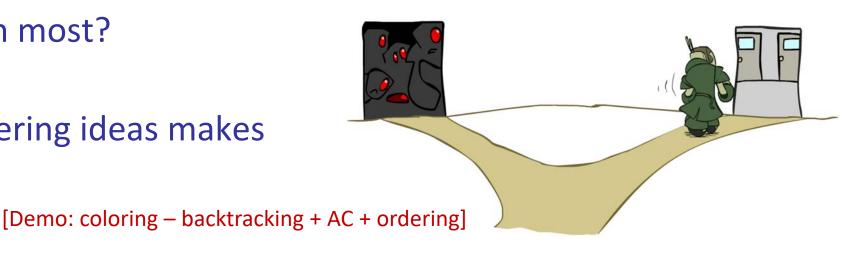

Ordering: Least Constraining Value

- Value Ordering: Least Constraining Value
 - Given a choice of variable, choose the *least* constraining value
 - I.e., the one that rules out the fewest values in the remaining variables
 - Note that it may take some computation to determine this! (E.g., rerunning filtering)

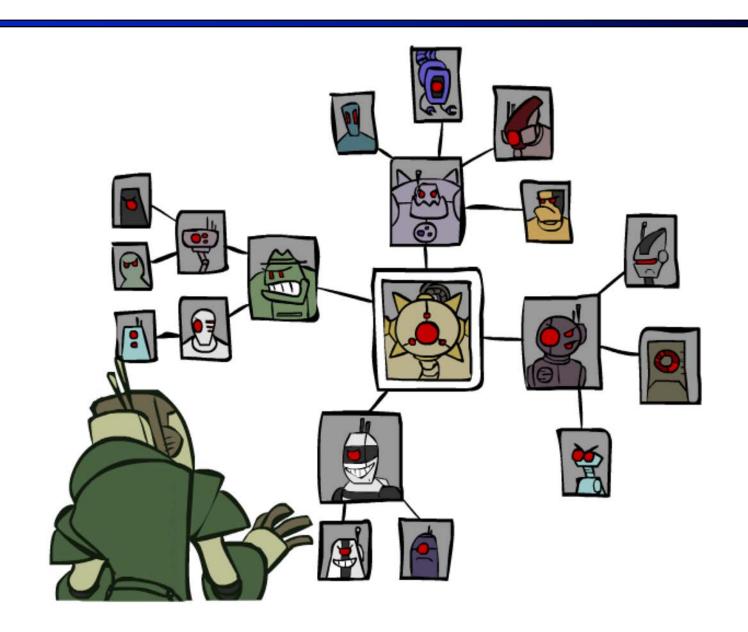

Combining these ordering ideas makes
1000 queens feasible

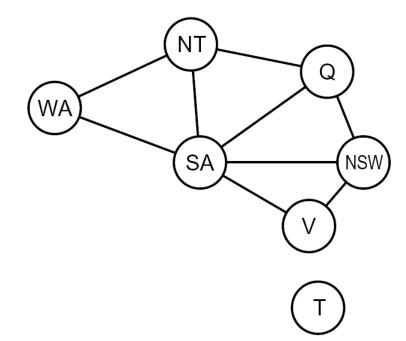

Structure

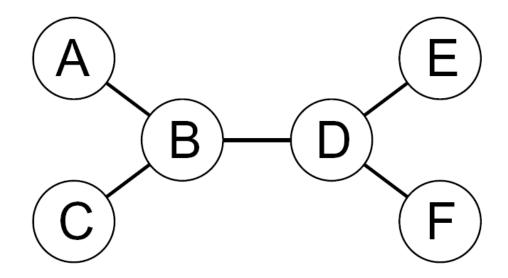

Problem Structure

- Extreme case: independent subproblems
 - Example: Tasmania and mainland do not interact
- Independent subproblems are identifiable as connected components of constraint graph
- Suppose a graph of n variables can be broken into subproblems of only c variables:
 - Worst-case solution cost is O((n/c)(d^c)), linear in n
 - E.g., n = 80, d = 2, c = 20
 - 2^{80} = 4 billion years at 10 million nodes/sec
 - $(4)(2^{20}) = 0.4$ seconds at 10 million nodes/sec

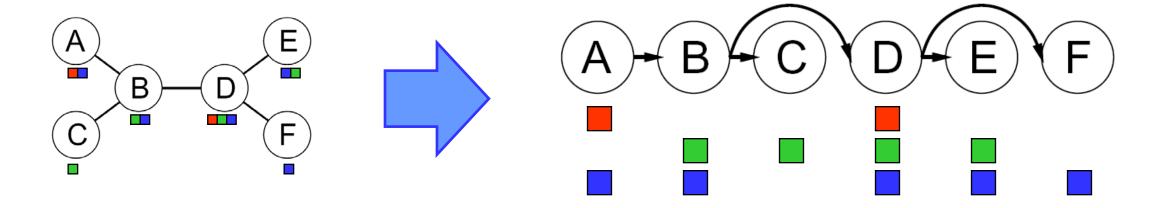

Tree-Structured CSPs

- Theorem: if the constraint graph has no loops, the CSP can be solved in O(n d²) time
 - Compare to general CSPs, where worst-case time is O(dⁿ)
- This property also applies to probabilistic reasoning (later): an example of the relation between syntactic restrictions and the complexity of reasoning

Tree-Structured CSPs

- Algorithm for tree-structured CSPs:
 - Order: Choose a root variable, order variables so that parents precede children

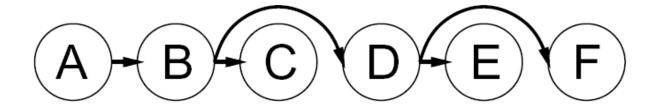

- Remove backward: For i = n : 2, apply RemoveInconsistent(Parent(X_i),X_i)
- Assign forward: For i = 1 : n, assign X_i consistently with Parent(X_i)
- Runtime: O(n d²)

Tree-Structured CSPs

- Claim 1: After backward pass, all root-to-leaf arcs are consistent
- Proof: Each X→Y was made consistent at one point and Y's domain could not have been reduced thereafter (because Y's children were processed before Y)

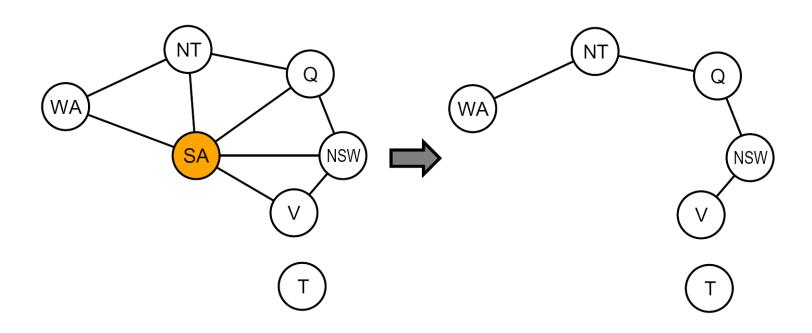

- Claim 2: If root-to-leaf arcs are consistent, forward assignment will not backtrack
- Proof: Induction on position
- Why doesn't this algorithm work with cycles in the constraint graph?
- Note: this basic idea is also used in Bayes' nets

Improving Structure

Nearly Tree-Structured CSPs

- Conditioning: instantiate a variable, prune its neighbors' domains
- Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree
- Cutset size c gives runtime O((d^c) (n-c) d²), very fast for small c

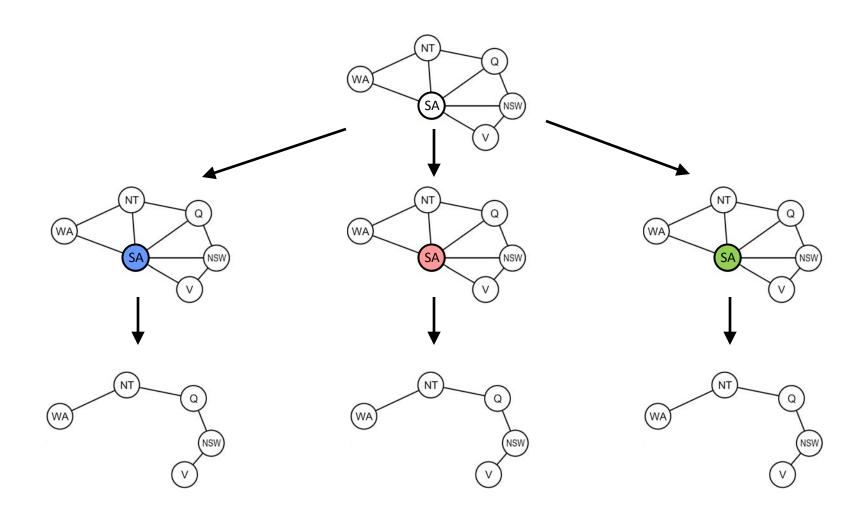

Cutset Conditioning

Choose a cutset

Instantiate the cutset (all possible ways)

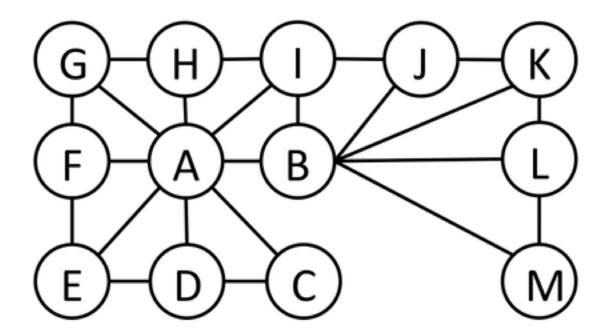

Compute residual CSP for each assignment

Solve the residual CSPs (tree structured)

Cutset Quiz

Find the smallest cutset for the graph below.

Exercise: Cutset

Consider a CSP with a constraint graph consisting of n variables arranged in a circle, where each variable has two constraints, one with each neighbor on either side. Explain how to solve this class of CSPs efficiently, in time O(n).

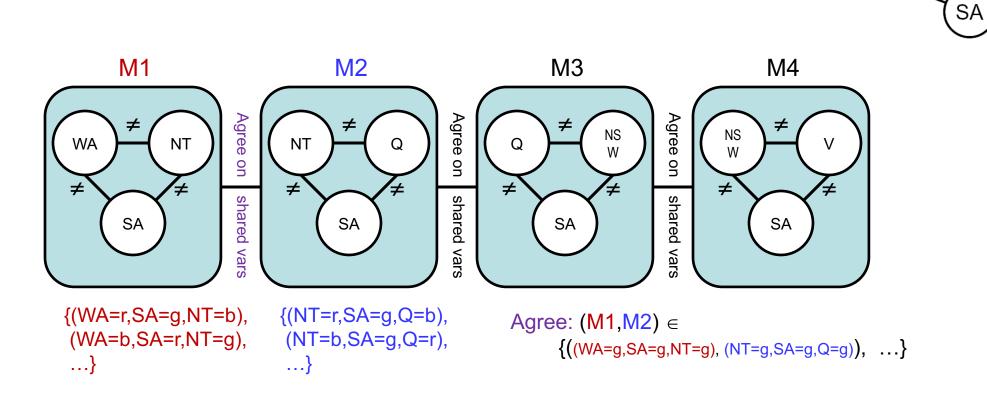

Tree Decomposition*

NT

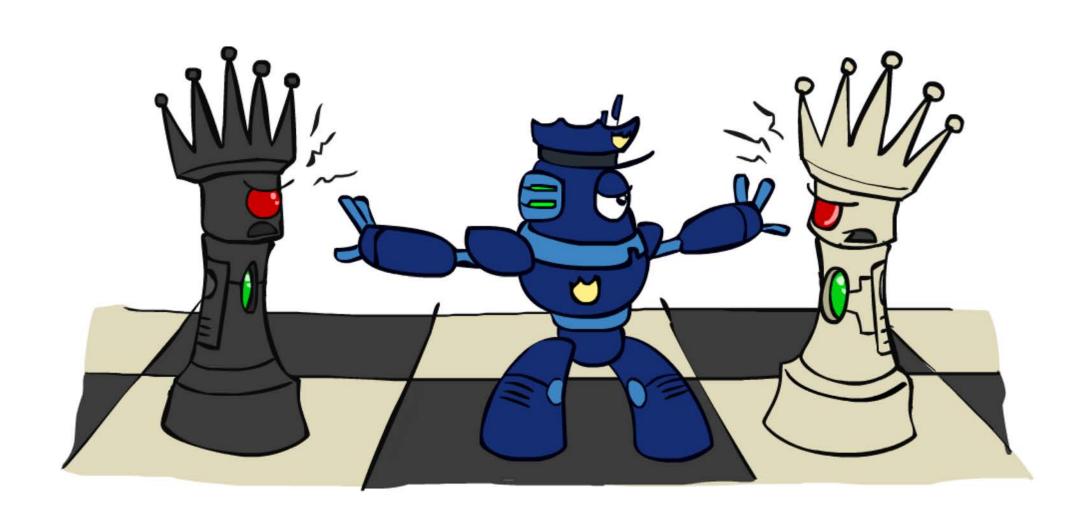

NSW

WA

- Idea: create a tree-structured graph of mega-variables
- Each mega-variable encodes part of the original CSP
- Subproblems overlap to ensure consistent solutions

Iterative Improvement

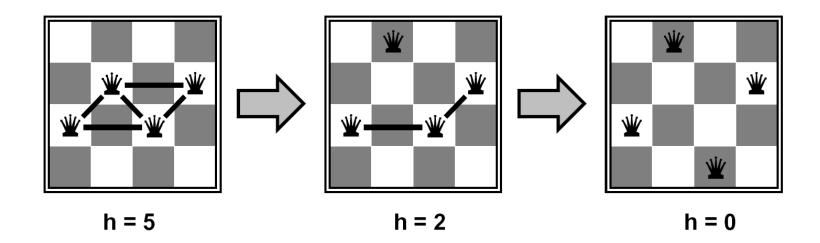

Iterative Algorithms (Local search) for CSPs

- Local search methods typically work with "complete" states, i.e., all variables assigned
- To apply to CSPs:
 - Take an assignment with unsatisfied constraints
 - Operators reassign variable values
 - No fringe! Live on the edge.

- Algorithm: While not solved,
 - Variable selection: randomly select any conflicted variable
 - Value selection: min-conflicts heuristic:
 - Choose a value that violates the fewest constraints
 - I.e., hill climb with h(n) = total number of violated constraints

Example: 4-Queens

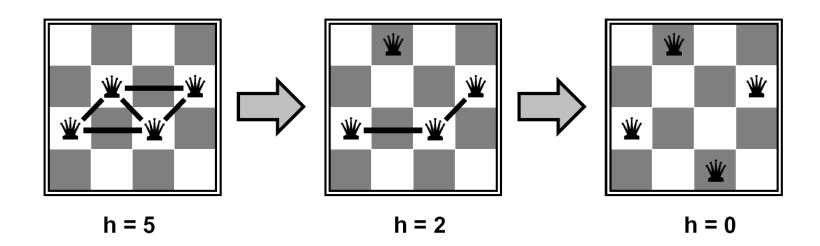

- States: 4 queens in 4 columns (4⁴ = 256 states)
- Operators: move queen in column
- Goal test: no attacks
- Evaluation: c(n) = number of attacks

[Demo: n-queens – iterative improvement (L5D1)]

[Demo: coloring – iterative improvement]

Example: 4-Queens

- States: 4 queens in 4 columns (4⁴ = 256 states)
- Operators: move queen in column
- Goal test: no attacks
- Evaluation: c(n) = number of attacks

[Demo: n-queens – iterative improvement (L5D1)]

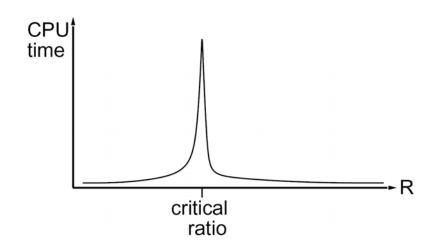

[Demo: coloring – iterative improvement]

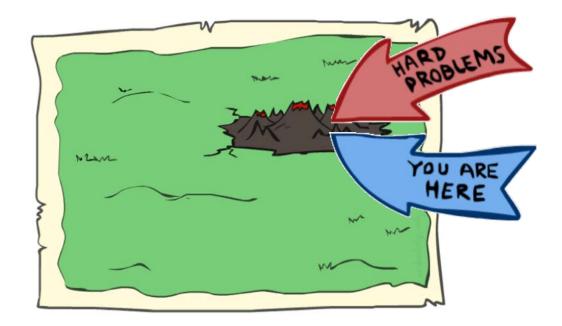

How does Min-conflicts work in practice?

Performance of Min-Conflicts

- Given random initial state, can solve n-queens in almost constant time for arbitrary n with high probability (e.g., n = 10,000,000)!
- The same appears to be true for any randomly-generated CSP except in a narrow range of the ratio

$$R = \frac{\text{number of constraints}}{\text{number of variables}}$$

(your own illustration within Project 2)

Completeness of local search

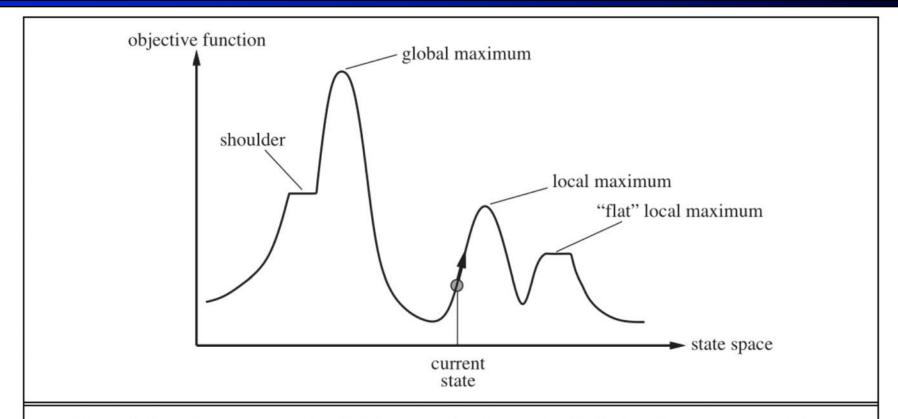

Figure 4.1 A one-dimensional state-space landscape in which elevation corresponds to the objective function. The aim is to find the global maximum. Hill-climbing search modifies the current state to try to improve it, as shown by the arrow. The various topographic features are defined in the text.

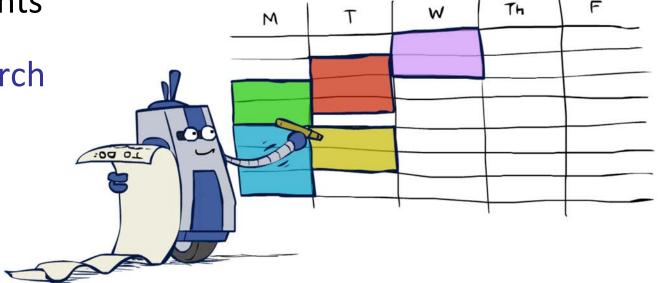

Hill climbing with random restart, simulated annealing, genetic algorithms

Summary: CSPs

- CSPs are a special kind of search problem:
 - States are partial assignments
 - Goal test defined by constraints

Basic solution: backtracking search

- Speed-ups:
 - Ordering
 - Filtering
 - Structure

Iterative min-conflicts is often effective in practice

HW: map coloring / performance

Generate random instances of map-coloring problems as follows: scatter n points on the unit square; select a point X at random, connect X by a straight line to the nearest point Y such that X is not already connected to Y and the line crosses no other line; repeat the previous step until no more connections are possible. The points represent regions on the map and the lines connect neighbors. Now try to find k-colorings of each map, for both k=3 and k=4, using min-conflicts, backtracking, backtracking with forward checking, and backtracking with MAC. Construct a table of average run times for each algorithm for values of n up to the largest you can manage. Comment on your results.

HW: Critical ratio

Using a CSP solver program and another program to generate random problem instances of CSPs, report on the time to solve the problem as a function of the ratio of the number of constraints to the number of variables.

Next Time: Adversarial Search!
