Numbers representation with computers, errors and uncertainties in computations

M. Peressi - UniTS - Laurea Magistrale in Physics
Laboratory of Computational Physics - Unit I - part II

Number representation in a given basis

A real number in basis 10:

$$741.36 = 7 \cdot 10^2 + 4 \cdot 10^1 + 1 \cdot 10^0 + 3 \cdot 10^{-1} + 6 \cdot 10^{-2}$$

If b is the basis, the string: $a_k a_{k-1} a_{k-2} \dots a_0 a_{-1} a_{-2} \dots a_{-k}$

represents: $\sum_{i=-k}^k a_i b^i = a_k b^k + a_{k-1} b^{k-1} + \dots + a_0 b^0 + a_{-1} b^{-1} + \dots + a_{-k} b^{-k}$

Another example: integer number, basis 2:

$$(1001)_2 = 1 \cdot 2^3 + 0 \cdot 2^2 + 0 \cdot 2^1 + 1 \cdot 2^0 = (9)_{10}$$

Number representation in a computer

- the microscopic unit of memory is the BIT=(0,1)

1 BYTE = 1B = 8 BITS

1K = 1KB= 2^{10} BYTES=1024 BYTES

- BIT=(0,1) => binary form for number representation
- the representation of a number in a computer is characterized by the numbers of bits used to store it
- fixed point or floating point representation
 - (for integers)
 - (for reals)

Fixed point representation for integers

$$(1001)_2 = 1 \cdot 2^3 + 0 \cdot 2^2 + 0 \cdot 2^1 + 1 \cdot 2^0 = (9)_{10}$$

- With **N bits**, typically the first one is reserved to the sign: **N-1** bits available =>

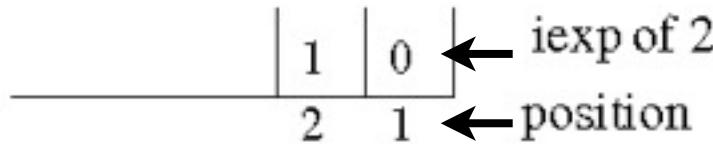

it is possible to represent numbers with absolute value in $[0, 2^{N-1}-1]$

If you try to go beyond: OVERFLOW
(i_min_max.f90)

Fixed point representation for integers

Assume 32 bits available: the result could be $[-2^{31}, 2^{31}-1]$; why?

| | | |
|----|----|--|
| 31 | 30 | |
| 32 | 31 | |

| | | |
|---|---|---|
| 0 | 1 | 1 |
| | | |

$$1 \mid 1 \mid 1 + (2^{30} + 2^{29} + \dots + 2^0) = 2^{31} - 1$$

| | | |
|---|---|---|
| 1 | 0 | 0 |
| | | |

$$0 \mid 0 \mid 0 - 2^{31}, \text{ NOT } +2^{31}, \text{ NOT } 0$$

| | | |
|---|---|---|
| 0 | 0 | 0 |
| | | |

$$0 \mid 0 \mid 0 \text{ this is } 0$$

| | | |
|---|---|---|
| 1 | 1 | 1 |
| | | |

$$1 \mid 1 \mid 1 - (2^{30} + 2^{29} + \dots + 2^0) = -(2^{31} - 1)$$

$$(2^{31} \sim 2 \times 10^9)$$

Floating point representation for real numbers

$$x_{\text{float}} = (-1)^s \bullet \underset{\substack{\text{sign} \\ |}}{\text{mantissa}} \bullet b^{\exp \text{fld} - \text{bias}}$$

significant figures of the number; exponent of the number; basis b=2

- Typically: **expfld** = 8-bit integer (goes from [0,255])
bias = 128 (or 127) => expfld-bias goes from -128 to +127 (or from -127 to +128) ;
23 bits reserved for the mantissa => tot 32 bits

$$\text{mantissa} = m_1 \cdot 2^{-1} + m_2 \cdot 2^{-2} + \dots + m_{23} \cdot 2^{-23} \quad (\text{m}_1 \text{ NOT } 0!)$$

- precision: $2^{-23} \approx 6\text{-}7$ decimal figures
- range : $\sim -10^{-39} - 10^{+38}$

examples of floating point representation for real numbers

| | | | | |
|-------------------|--|---|----------|-----------------------------------|
| $\frac{1}{2} = 0$ | $0111 \underbrace{\quad}_{\text{segno}} \underbrace{\quad}_{\text{Expfld=127}} \underbrace{\quad}_{\text{Expldf-bias =0}}$ | $1111 \underbrace{\quad}_{\text{(here: bias=127)}}$ | 2^{-1} | 1000 0000 0000 0000 0000 0000 000 |
| $6 = 0$ | $1000 \underbrace{\quad}_{\text{segno}} \underbrace{\quad}_{\text{Expfld=130}} \underbrace{\quad}_{\text{Expldf-bias =3}}$ | $0010 \underbrace{\quad}_{\text{Expfld=127}}$ | 2^{-1} | 1100 0000 0000 0000 0000 0000 000 |

the smallest: (if mantissa is in the normalized form, i.e., first number $=/ \neq 0$)

$$0 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 0000 \ 000 = 2^{-128} = 2.9 \times 10^{-39}$$

Expfld=0
Expfld-bias= - 127

the largest:

$$0 \ 1111 \ 1111 \ 1111 \ 1111 \ 1111 \ 1111 \ 1111 \ 111 \approx 2^{128} \approx 3.4 \times 10^{38}$$

Expfld=2^8-1
Expfld-bias= 128

$2^0 - 2^{-23} \sim 1$

single and double precision

For **double precision**:

- Typically: **expfld** = 11-bit integer (goes from [0,2047])
bias = 1023 => expfld-bias goes from -1023 to +1024 ;
52 bits reserved for the mantissa => tot 64 bits
- precision: $2^{-52} \sim= 15\text{-}16$ decimal figures
- range : $\sim -10^{-322} - 10^{+308}$

If you try to go beyond these limits (see `rs(d)_under_over.f90`):
UNDERFLOW (too small) and OVERFLOW (too large)

Roundoff errors

$$7 + 1.0 \times 10^{-9} = ???$$

Single precision representation:

$$\begin{array}{llllllllll} 7 = 0 & 1000 & 0010 & 1110 & 0000 & 0000 & 0000 & 0000 & 000 \\ 10^{-9} = 0 & 0110 & 0000 & 1101 & 0110 & 1011 & 1111 & 1001 & 010 \end{array}$$

(here: bias=127)

Exponents are different! Make them equal before operating on the mantissas: increase the smallest exponent, but at the same time reduce the corresponding mantissa:

| $\times 2$ (i.e., +1 in expfield) | :2 (right hand-side shift of the bits) | (bits lost) |
|-----------------------------------|---|-------------|
| $10^{-9} = 0 \quad 0110 \ 0001$ | $0110 \ 1011 \ 0101 \ 1111 \ 1100 \ 101$ | (0) |
| $= 0 \quad 0110 \ 0010$ | $0011 \ 0101 \ 1010 \ 1111 \ 1110 \ 010$ | (10) |
|, | | |
| $= 0 \quad 1000 \ 0010$ | $0000 \ 0000 \ 0000 \ 0000 \ 000 \quad (0001101 ...)$ | |

$$7 + 1.0 \times 10^{-9} = 7 \quad !!!$$

Machine precision

The smallest number that, added to 1 represented in the machine, does not change it:

$$\varepsilon_m + 1_c = 1_c$$

$\varepsilon \approx 10^{-7}$ single precision

$\varepsilon \approx 10^{-16}$ double precision

Note: IT IS NOT the smallest representable number!

See also: intrinsic function epsilon(x)

Source of errors in numerical computing

- Human
- Random (e.g. electrical fluctuations)

- Roundoff
- Truncation

$$2\left(\frac{1}{3}\right) - \frac{2}{3} = 2 \times 0.3333333 - 0.6666667 = -0.0000001 \neq 0.$$

$$e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!} \cong \sum_{n=0}^N \frac{x^n}{n!} = e^x + E(x, N)$$

Mainly ROUND OFF,
due to the finite representation of numbers
in a computer

See also: <https://floating-point-gui.de/>

An example of roundoff+truncation

Numerical derivatives

Calculate the derivative of:

$$f(x) = \sin(x) \text{ in } x = 1$$

We call: $f_0 = f(x), f_1 = f(x + h), \text{ e } f_{-1} = f(x - h)$.

We can use several algorithms:

$$f'(x) \sim \frac{f_1 - f_{-1}}{2h} \quad (=f'_{\text{simm}})$$

$$f'(x) \sim \frac{f_1 - f_0}{h} \quad (=f'_{\text{ds}})$$

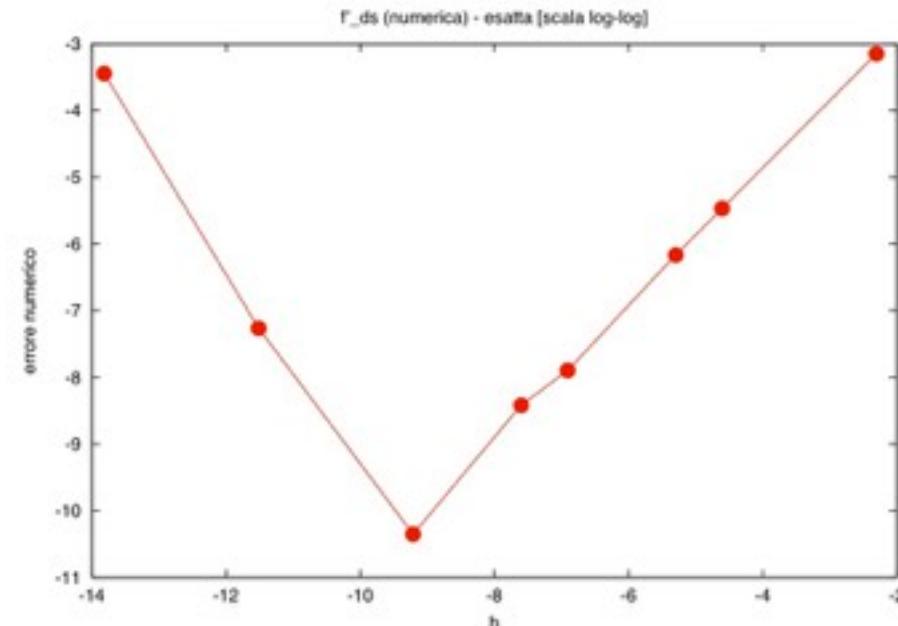

$$f'(x) \sim \frac{f_0 - f_{-1}}{h} \quad (=f'_{\text{sin}})$$

Make numerical experiments with h and progressively reduce it ...

An example of roundoff+truncation

Numerical derivatives

| h | f'_{ds} | f'_{ds} -exact | f'_{\sin} | f'_{\sin} -exact | f'_{simm} | f'_{simm} -exact |

- The symmetric algorithm is the best
 - By reducing h down to $\sim 10^{-4}$ the numerical error decreases, but further reduction of h does not improve the result, or better, the result is even worse!
- Why? **roundoff error**

Other possible sources of errors due to roundoff

- subtraction between very large numbers ($\infty - \infty$)
(a “bad” example: calculate $\exp(-x)$ for $x > 1$ with the standard series with alternate sign)

expressions analytically equivalent
can be NOT numerically equivalent!

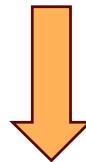

$$\sum_{n=1}^{2N} (-1)^n \frac{n}{n+1}$$

BAD!

for large N:
subtraction between
very large numbers ($\infty - \infty$)

$$<0 \quad >0$$

$$\sum_{n=1}^N \frac{1}{2n(2n+1)}$$

OK!

How does your computer make a calculation?

(remember... this is a common source
of HUMAN error in coding)

In Fortran:

$I/2 = ???$ 0 !!! **WRONG**

since this operation is done within the **INTEGERS**

$I./2 = ???$ 0.5 !!! **CORRECT**

since 2 is promoted to **REAL** and the operation is
done within the **REALS**
