Bioconstructions

Biogenic reefs are produced by the activity of skeleton producing organisms such as calcareous algae, oysters and corals. Calcareous sediments deriving from algae, mollusc shells, echinoderms spines, sponge spicules and other skeletal debris often fill the spaces within the reef framework and become consolidated in various ways. Sponges, zoanthids and certain colonial ascidians can bind reef materials together. Organisms that grow as calcareous sheets can act as biological cementing agents, building permanent bonds that cause the strong adhesion of loose calcareous sediments to the reef frame.

Bioconstructions

Bioconstructors modify primary (i.e. geological) substrates and provide secondary (i.e. biogenic) substrates for new bioconstructors and for nonbioconstructors who simply inhabit them

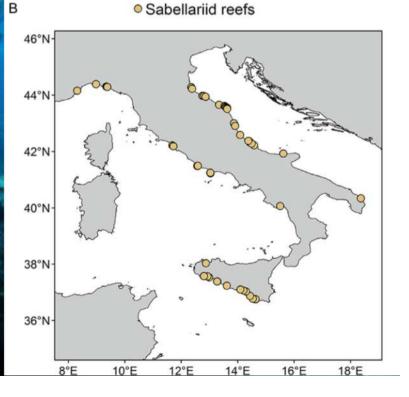

Bioconstructions of the Mediterranean Sea

- Lithophyllum byssoides
 concretions/trottoirs
- Astroides calycularis formations/reefs
- Coralligenous assemblages
- Cladocora caespitosa formations/reefs
- Vermetid reefs
- Sabellariid reefs
- Cold-water corals
- Serpulid reefs, including biostalactites

Sabellariid reefs are compact bioconstructions resulting from the aggregation of tubes made up of sand grains and bioclasts, cemented with mucus, which develop on both solid and soft bottoms. The worms construct these tubes around themselves, in close proximity

Biostalactites

C • Submarine biostalactites

Particular serpulid structures in submarine caves are the so called biostalactites. They are formed by single or few serpulid species (mostly Protula spp.) whose aggregations become substrate for smaller invertebrates and bacteria. **Biostalactites** can protrude a few cm up to 2 m.

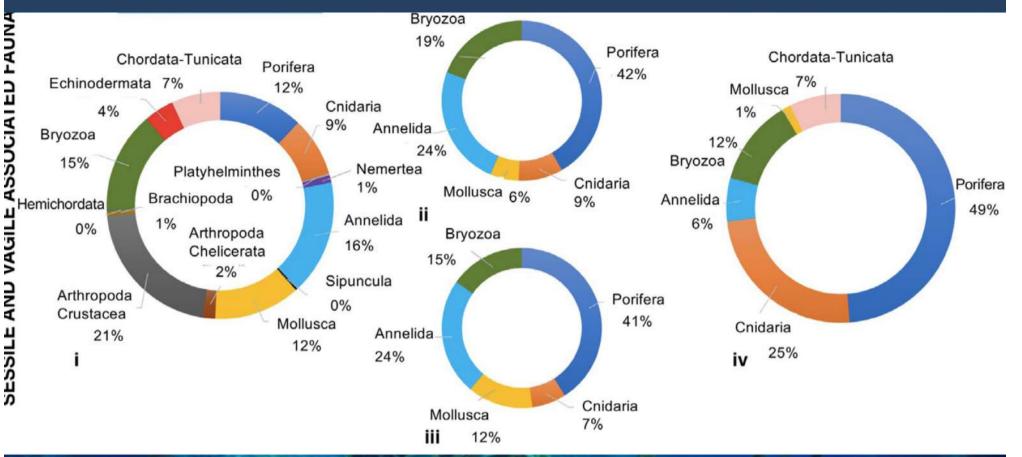

A

Coralligenous reef is a hard substratum of biogenic origin that is mainly produced by the accumulation of calcareous encrusting corallines (red algae, **Rhodophyta)** growing under dim light conditions. It often develops on almost vertical walls, on gently sloping bottoms or near the base of a wall. **Coralligenous formations** consist of carbonatic concrections whose thicknesses range from 25 cm to more than 2 m.

В

It can also form platforms (from tens of cms to several m) on the continental shelf. Mediterranean rocky bottoms from 15 to 130 m depth, depending on water transparency.

Different types of bioconcrections are present depending on the main components, which in turn, depends on environmental features such as distance from the coasts and human influence

Falace et al., 2015

In the northern Adriatic continental shelf, biogenic frameworks are

generally superimposed on hard bottoms. Marine sediments may be consolidated by methanerelated calcium carbonate cementation, thanks to seepage of CH₄-rich fluids, observable near many offshore reefs. Pleistocenic rivers, Holocene tidal channels and beach bars which are initial substrate for current coralligenous build-ups.

Distribution

Surface areas reported here for coralligenous outcrops (2,763 km²) based on data resulting from *in situ* observations limited to the 0 to 200 m depth band. Martin et al. 2014

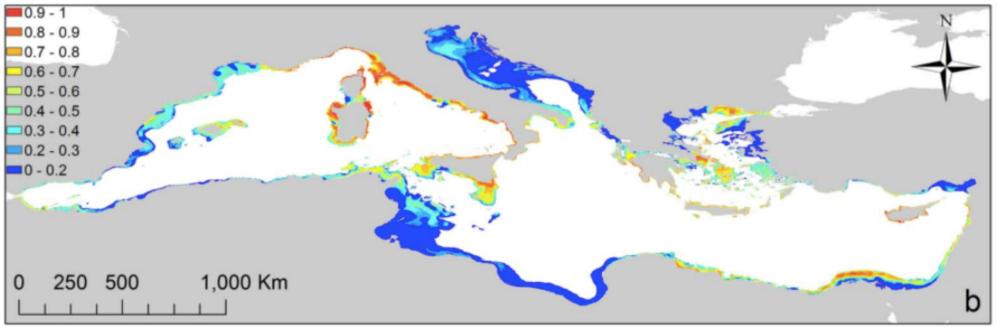

Maërl

Biogenic structure formed by several coralline algae growing and accumulating (dead and alive) on soft bottom, living unattached to the substrate with thalli as nodules of ramified shapes. Algae can live >100 y. *Phymatolithon calcareum*

MMEs

Paramuricea clavata monitored during five years (2014–2019, Tremiti Islands). Massive mucilagenous blooms occurred from 2015 until 2018. The gorgonians at 30-40 m were entirely covered with mucilage. Below 40 m colonies were almost unaffected. Chimienti et al. 2021
