  - Greedy Search
  - A\* Search

# Recap: Search

### Recap: Search

#### Search problem:

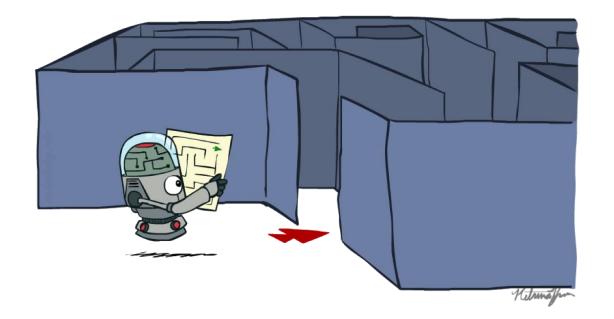

- States (configurations of the world)
- Actions and costs
- Successor function (world dynamics)
- Start state and goal test

#### Search tree:

- Nodes: represent plans for reaching states
- Plans have costs (sum of action costs)

#### Search algorithm:

- Systematically builds a search tree
- Chooses an ordering of the fringe (unexplored nodes)
- Optimal: finds least-cost plans

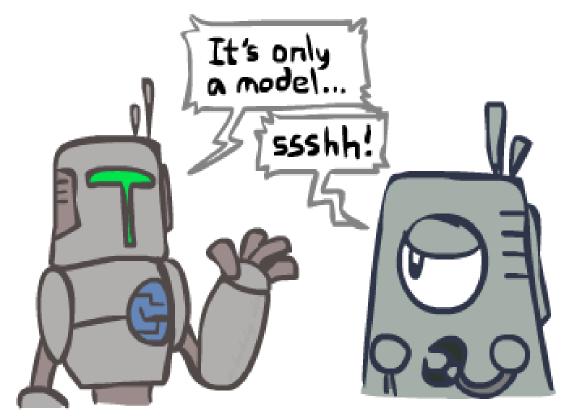

#### The One Queue

- ★ All these search algorithms are the same except for fringe strategies
  - ★ Conceptually, all fringes are priority queues (i.e. collections of nodes with attached priorities)
  - → Practically, for DFS and BFS, you can avoid the log(n) overhead from an actual priority queue, by using stacks and queues
  - ★ Can even code one implementation that takes a variable queuing object

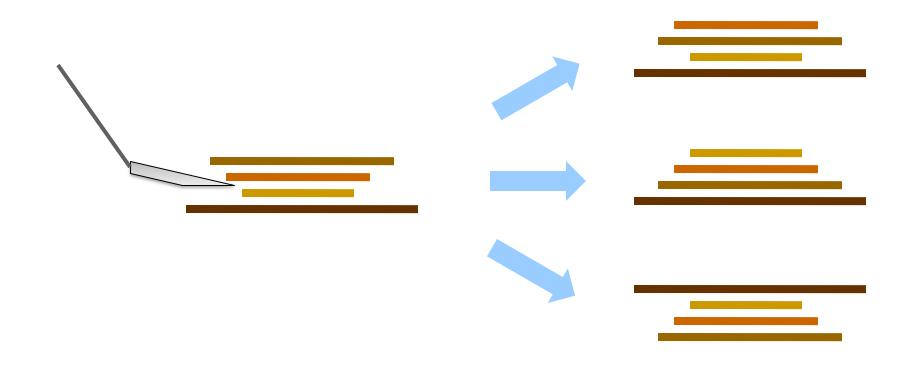

#### Search and Models

- ★Search operates over models of the world
  - ★The agent doesn't actually try all the plans out in the real world!
  - ✦Planning is all "in simulation"
  - ◆Your search is only as good as your models...

# Example: Pancake Problem

Cost: Number of pancakes flipped

### Example: Pancake Problem

#### BOUNDS FOR SORTING BY PREFIX REVERSAL

William H. GATES

Microsoft, Albuquerque, New Mexico

Christos H. PAPADIMITRIOU\*†

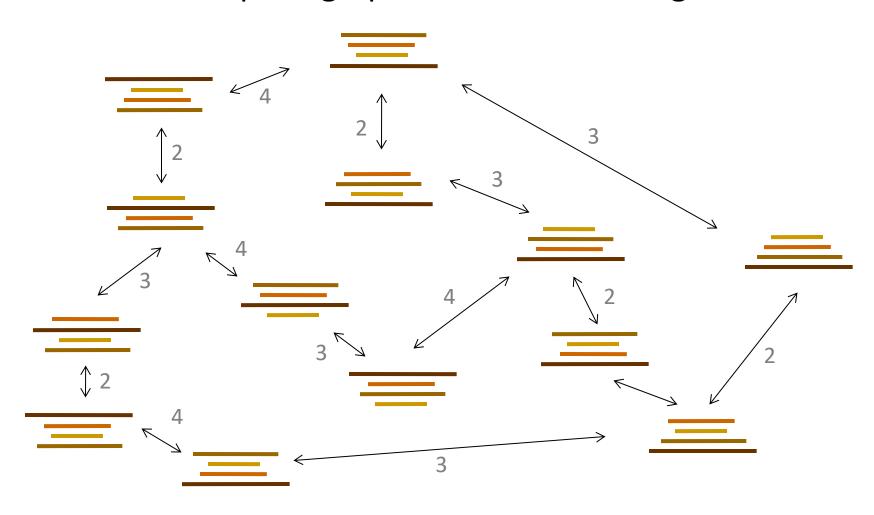

Department of Electrical Engineering, University of California, Berkeley, CA 94720, U.S.A.

Received 18 January 1978 Revised 28 August 1978

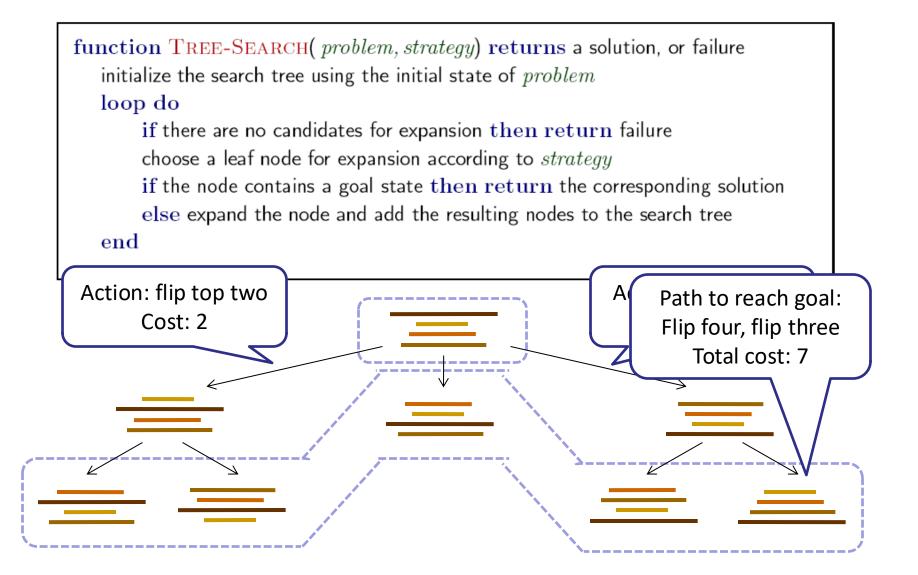

For a permutation  $\sigma$  of the integers from 1 to n, let  $f(\sigma)$  be the smallest number of prefix reversals that will transform  $\sigma$  to the identity permutation, and let f(n) be the largest such  $f(\sigma)$  for all  $\sigma$  in (the symmetric group)  $S_n$ . We show that  $f(n) \leq (5n+5)/3$ , and that  $f(n) \geq 17n/16$  for n a multiple of 16. If, furthermore, each integer is required to participate in an even number of reversed prefixes, the corresponding function g(n) is shown to obey  $3n/2 - 1 \leq g(n) \leq 2n + 3$ .

## Example: Pancake Problem

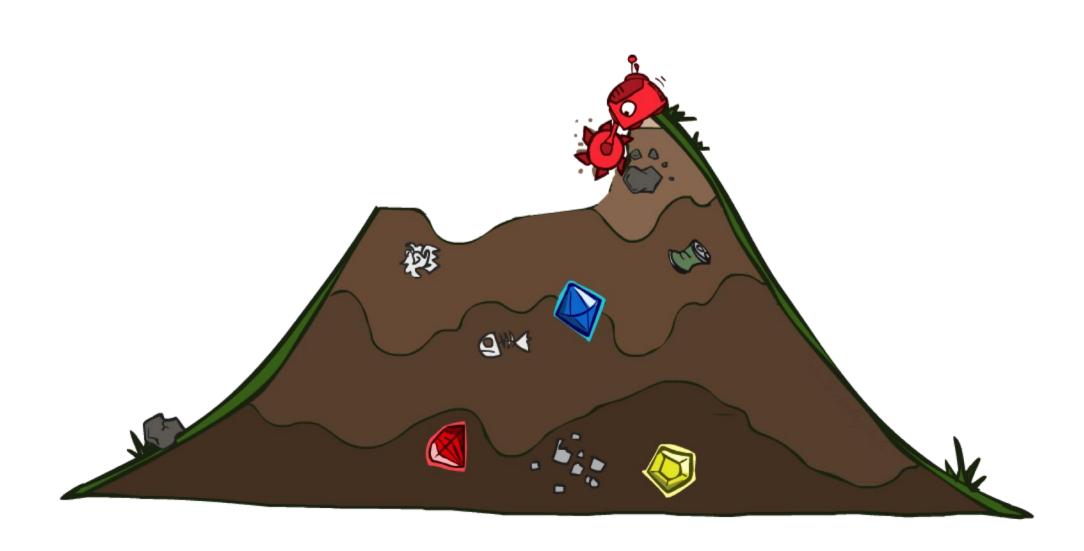

State space graph with costs as weights

#### General Tree Search

## **Uninformed Search**

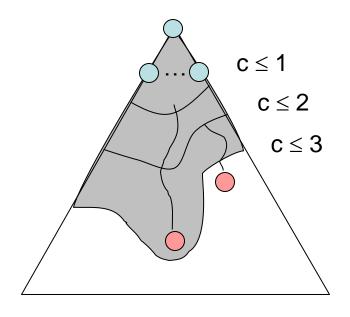

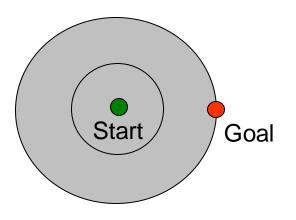

#### **Uniform Cost Search**

Strategy: expand lowest path cost

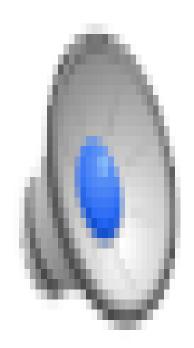

The good: UCS is complete and optimal!

- The bad:
  - Explores options in every "direction"
  - No information about goal location

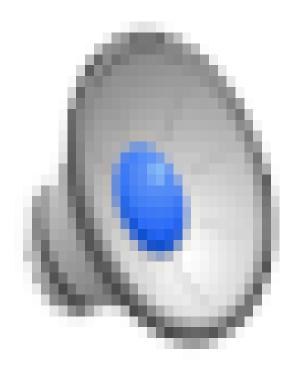

# Video of Demo Contours UCS Empty

### Video of Demo Contours UCS Pacman Small Maze

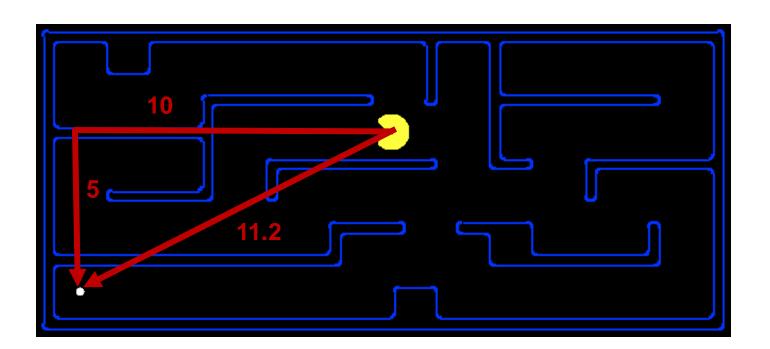

## Informed Search

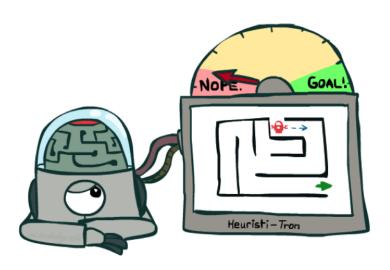

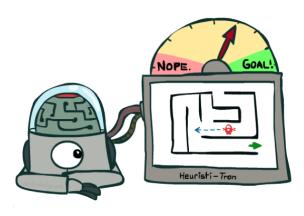

#### **Search Heuristics**

#### • An heuristic function h(n):

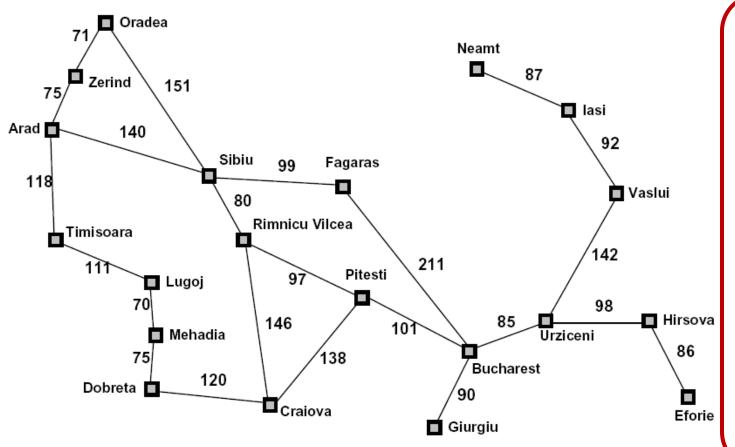

- Estimates how close a state n is to a goal
- Designed for a particular search problem
- Examples: Manhattan distance, Euclidean distance for pathing

## **Example: Heuristic Function**

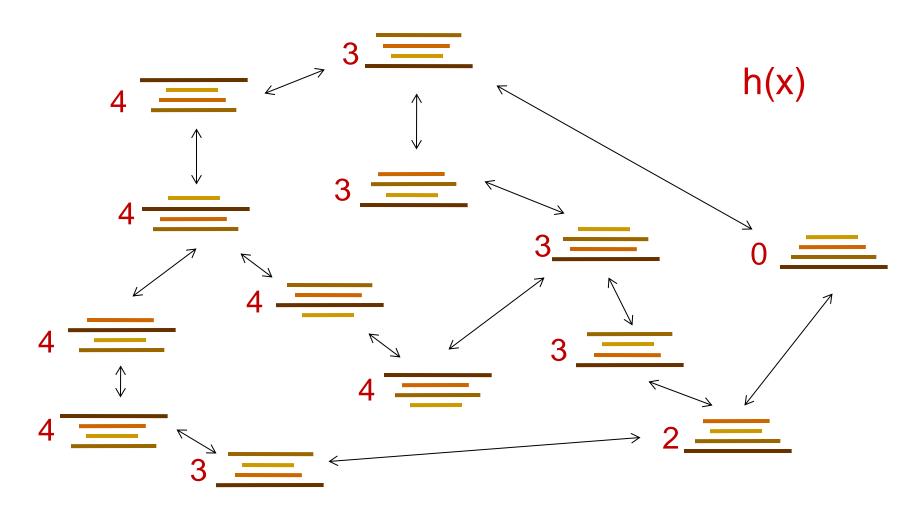

Straight-line distance to Bucharest	
Arad	366
Bucharest	0
Craiova	160
Dobreta	242
Eforie	161
Fagaras	178
Giurgiu	77
Hirsova	151
Iasi	226
Lugoj	244
Mehadia	241
Neamt	234
Oradea	380
Pitesti	98
Rimnicu Vilcea	193
Sibiu	253
Timisoara	329
Urziceni	80
Vaslui	199
Zerind	374

## **Example: Heuristic Function**

Heuristic: the number of the largest pancake that is still out of place

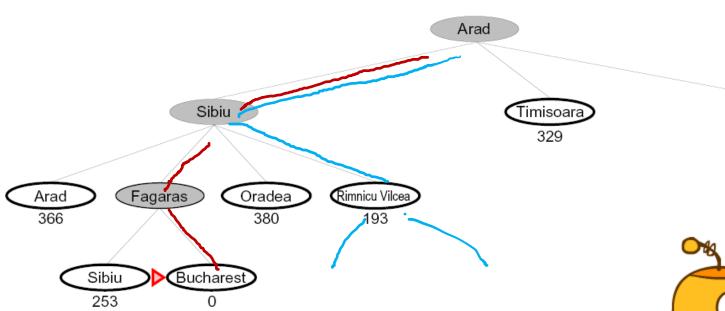

# **Greedy Search**

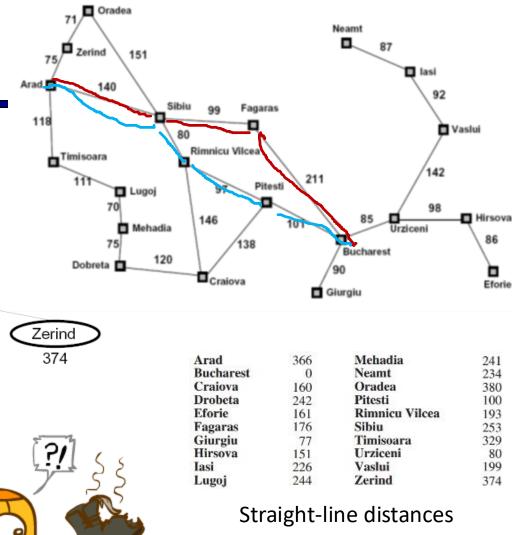

### **Greedy Search**

• Expand the node that seems closest... i.e. evaluation function f(n) = h(n)

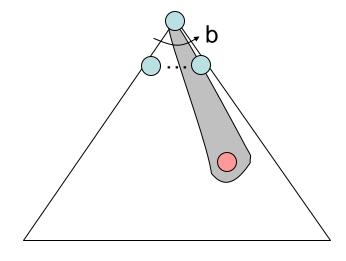

What can go wrong?

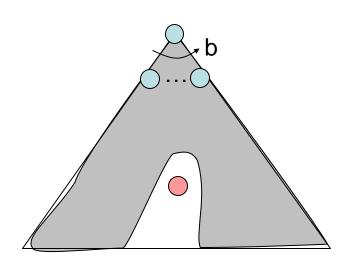

### **Greedy Search**

- Strategy: expand a node that you think is closest to a goal state
  - Heuristic: estimate of distance to nearest goal for each state

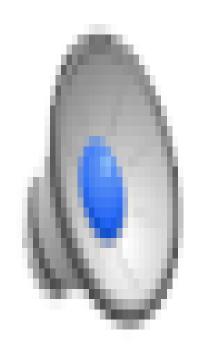

- A common case:
  - Best-first takes you straight to the (wrong) goal

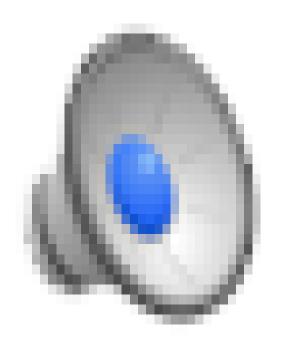

Worst-case: like a badly-guided DFS

# Video of Demo Contours Greedy (Empty)

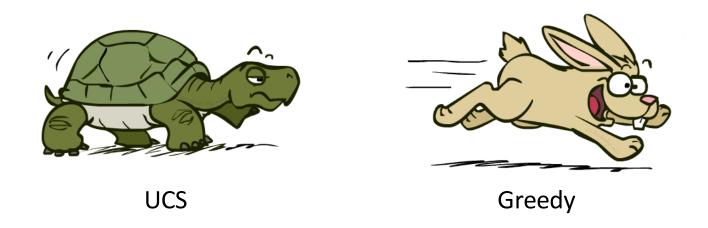

#### Video of Demo Contours Greedy (Pacman Small Maze)

# A\* Search

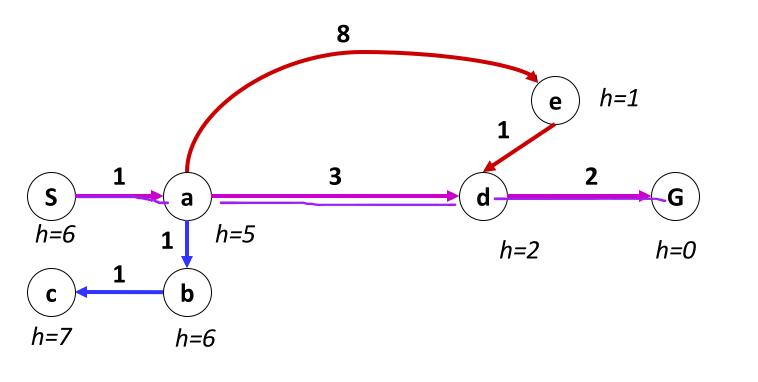

# A\* Search

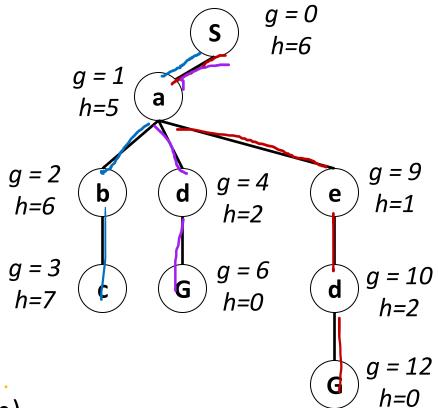

## Combining UCS and Greedy

- Uniform-cost orders by path cost, or backward cost g(n)
- Greedy orders by goal proximity, or forward cost h(n)

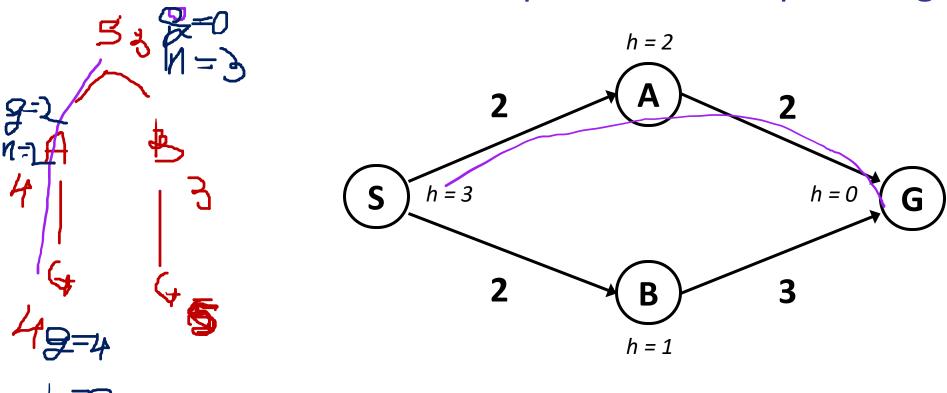

• A\* Search orders by the sum: f(n) = g(n) + h(n)

Example: Teg Grenager

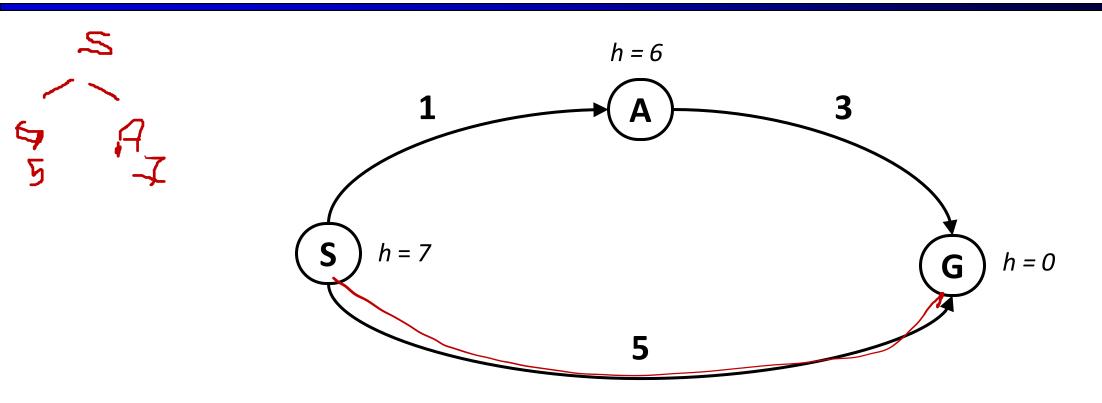

#### When should A\* terminate?

Should we stop when we enqueue a goal?

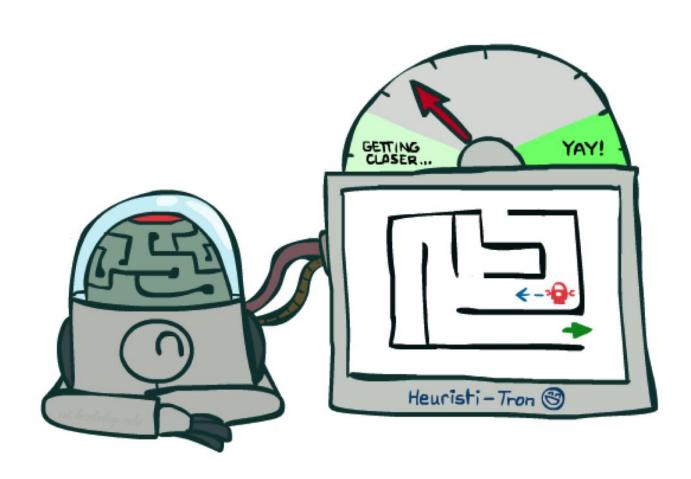

No: only stop when we dequeue a goal

#### Is A\* Optimal?

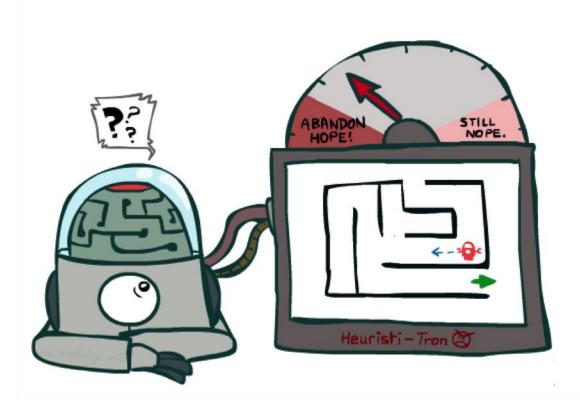

- What went wrong?
- Actual bad goal cost < estimated good goal cost</li>
- We need estimates to be less than actual costs!

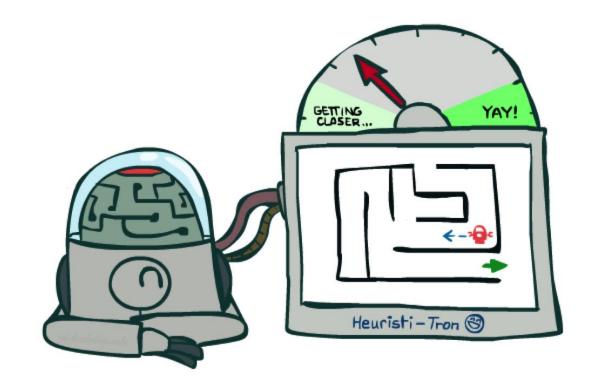

### Admissible Heuristics

### Idea: Admissibility

Inadmissible (pessimistic) heuristics break optimality by trapping good plans on the fringe

Admissible (optimistic) heuristics slow down bad plans but never outweigh true costs

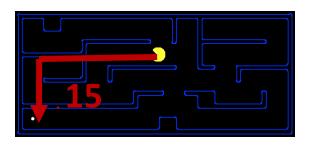

#### Admissible Heuristics

A heuristic h is admissible (optimistic) if:

$$0 \le h(n) \le h^*(n)$$

where  $h^*(n)$  is the true cost to a nearest goal

• Examples:

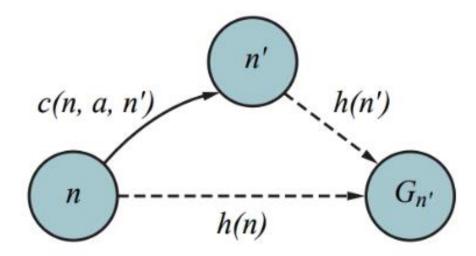

4

 Coming up with admissible heuristics is most of what's involved in using A\* in practice.

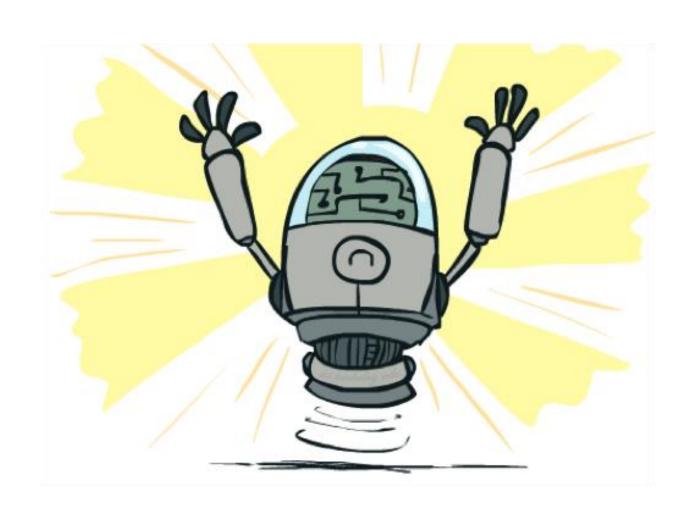

#### **Consistent Heuristics**

• A heuristic h is consistent if, for every node n and every successor n' of n generated by an action a, we have:

$$h(n) \le c(n, a, n') + h(n')$$

# Optimality of A\* Tree Search

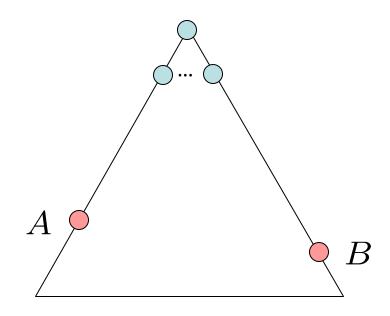

# Optimality of A\* Tree Search

#### Assume:

- A is an optimal goal node
- B is a suboptimal goal node
- h is admissible

#### Claim:

A will exit the fringe before B

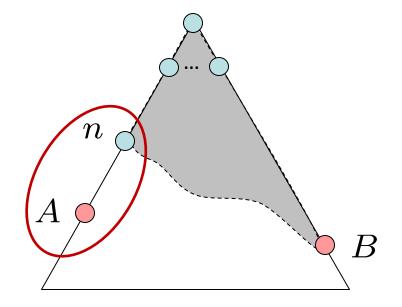

# Optimality of A\* Tree Search: Blocking

#### Proof:

- Imagine B is on the fringe
- Some ancestor n of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B

1. 
$$f(n) \leq f(A)$$

# Optimality of A\* Tree Search: Blocking

#### 1. $f(n) \leq f(A)$

Definition of f-cost says:

$$f(n) = g(n) + h(n) = (path cost to n) + (est. cost of n to A)$$
  
 $f(A) = g(A) + h(A) = (path cost to A) + (est. cost of A to A)$ 

■ The admissible heuristic must underestimate the true cost h(A) = (est. cost of A to A) = 0

$$f(n) = g(n) + h(n)$$
  
$$f(A) = g(A)$$

• h(n) must be an underestimate of the true cost from n to A

$$g(n) + h(n) \le g(A)$$

$$f(n) \le f(A)$$

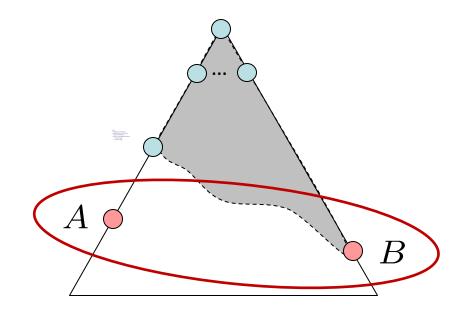

#### Optimality of A\* Tree Search: Blocking

#### Proof:

- Imagine B is on the fringe
- Some ancestor n of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B

1. 
$$f(n) \leq f(A)$$

2. 
$$f(A) \leq f(B)$$

#### Optimality of A\* Tree Search: Blocking

2. 
$$f(A) \leq f(B)$$

We know that:

$$f(A) = g(A) + h(A) =$$
(path cost to A) + (est. cost of A to A)  $f(B) = g(B) + h(B) =$ (path cost to B) + (est. cost of B to B)

■ The heuristic must underestimate the true cost:

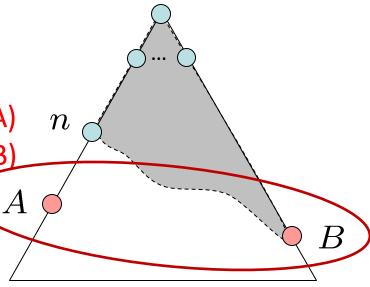

$$h(A) = h(B) = 0$$

So now, we have to compare:

$$f(A) = g(A)$$
$$f(B) = g(B)$$

We assumed that B is suboptimal! So

$$g(A) < g(B)$$
  
$$f(A) < f(B)$$

#### Optimality of A\* Tree Search: Blocking

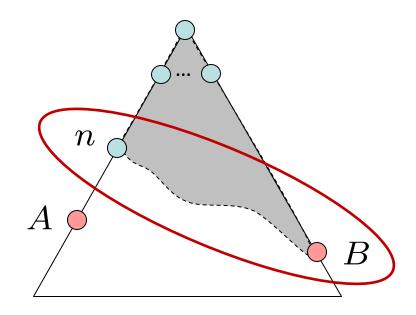

#### Proof:

- Imagine B is on the fringe
- Some ancestor n of A is on the fringe, too (maybe A!)
- Claim: n will be expanded before B

1. 
$$f(n) \leq f(A)$$

2. 
$$f(A) < f(B)$$

- 3. n expands before B —
- All ancestors of A expand before B
- A expands before B
- A\* search is optimal

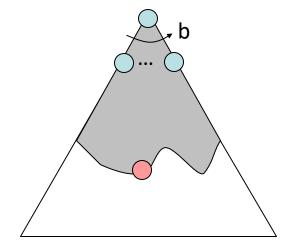

$$f(n) \le f(A) < f(B)$$

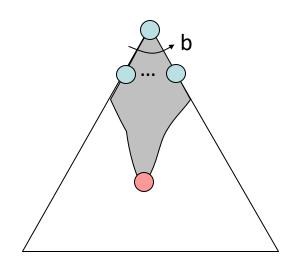

# Properties of A\*

## Properties of A\*

**Uniform-Cost** 

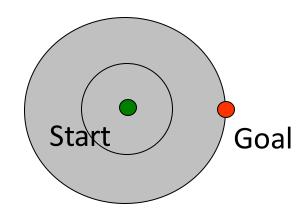

Δ\*

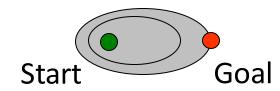

#### UCS vs A\* Contours

 Uniform-cost expands equally in all "directions"

 A\* expands mainly toward the goal, but does hedge its bets to ensure optimality
