tively. The signals for pyrazine in asymmetric complex **3c**•pyrazine consisted of two *meta*-split doublets at 4.31 ( $J = 1$  Hz) and 4.35 ppm ( $J = 1$  Hz).<sup>16</sup> This confirms that pyrazine is oriented in complex **3b**•pyrazine with its nitrogens at the equator and its hydrogens extending into the bowls (structure **A**, Figure 3). The activation energy for rotation of pyrazine about the pseudo- $C_2$  axes in asymmetric complex **3c**•pyrazine was measured by variable-temperature  $^1\text{H}$  NMR spectroscopy to be 18 kcal/mol,<sup>17</sup> which agrees well with the 19 kcal/mol activation

(17) The activation barrier for rotation of pyrazine about the pseudo- $C_2$  axes of asymmetric complex **3c**•pyrazine was calculated to be 18.3 kcal/mol based on a coalescence temperature ( $T_c$ ) of 353 K and separation of the signals ( $\Delta\delta_{\text{Hz}}$ ) of 14.3 Hz using the following equation:  $\Delta G_c^\ddagger = RT_c - [22.96 + \ln(T_c/\Delta\delta_{\text{Hz}})]$  where  $\Delta G_c^\ddagger$  is the activation barrier in kcal/mol;  $T_c$  is the temperature of coalescence, and  $\Delta\delta_{\text{Hz}}$  is the separation of the signals in Hz. See: Abraham, R. J.; Fisher, J.; Loftus, P. *Introduction to NMR Spectroscopy*; Wiley: New York, 1990; pp 194–197.

A

guests. In host–guest systems, there are two energetic quantities associated with guest binding—constrictive and intrinsic binding. The constrictive binding<sup>11,12</sup> is the activation energy required for a guest to enter the host, while intrinsic binding is the change in energy upon formation of the host–guest complex from free host and guest. Intrinsic binding energy determines the equilibrium constant for binding; the intrinsic binding energy plus the constrictive binding energy determines the kinetic barrier to decomplexation.<sup>12</sup>

Intrinsic binding, the free energy of complexation, depends on the magnitude of the noncovalent interactions between the guest and the host's inner surface.

Constrictive binding, activation energy required for a guest to enter OR exit the inner cavity of a hemicarcerand through a size restricting portal in the host's skin.

Constrictive binding: aumenta con le dimensioni del guest, diminuisce con le dimensioni dei portali, e con l'aumento della flessibilità dei linker (T).

**Gating:** Gating in host-guest chemistry refers to conformational changes that occur in response to some stimulus, resulting in opening or closing of a physical barrier that controls access to the host.

Figure S2: Molecular modelling of complexation of **4** with propofol (2,6-diisopropylphenol) using Schrödinger Macromodel (OPLS\_2005, GB/SA  $\text{CHCl}_3$ ). (The geometry began with the guest inside the host; the guest came out of the host after the minimization)

In summary, a new reversible photoswitchable gated hemicarcerand containing two anthracene groups was designed and synthesized. The photochemical properties of this system were studied by  $^1\text{H}$  NMR and fluorescence spectroscopy. The photoswitchable cycle between the open (hemicarcerand) and closed (carcerand) states of the host is well controlled by radiation of different wavelengths, and controlled encapsulation and release of the guest molecules such as 1,4-dimethoxybenzene was observed. We are currently working on enlarging the cavity size of the host as well as increasing the water solubility of the host.

## From molecular mechanics calculations:

the encapsulated guest(s) occupy approximately 55% of the available space (same occupancy inside most weakly interacting organic solvents).

Stability decreases at higher or lower space occupancy.

# The ins and outs of molecular encapsulation

Liam C. Palmer and Julius Rebek, Jr.\*

*Org. Biomol. Chem.*, 2004, 2, 3051–3059

A priori, two plausible exchange mechanisms can be imagined: (1) a dissociative mechanism in which the two capsule subunits completely separate, or (2) a gating mechanism<sup>22</sup> whereby one “flap” of the tennis ball opens by ring inversion of the seven-membered ring (as shown in Fig. 5).

**Fig. 5** The intact tennis ball, left, and the conformation with an open flap, right. The structure on the right represents intermediate of a possible “gating” mechanism.

Small guests like toluene can escape by opening of a single flap, left. Larger guests like dimethylbiphenyl require opening of two or more flaps, right.

Contrasting the mechanism in apolar media, the presence of methanol seems to cause large guest exchange by complete dissociation of the capsule subunits. Complexes of small guests are not stable under these conditions.

Model structure: incapsulation of coiled alkanes - tetradecane

## *Social Isomers:*

A new form of isomerism arises when two different guests are confined to a cylindrical, self-assembled host capsule. The shape and dimensions of the capsule prevent the guests from exchanging positions or tumbling on the NMR time scale. The phenomenon depends on matching guest size and shape with that of the host and on the interaction of the two guest molecules. The orientation of one guest depends on the presence and nature of the other.

# Social Isomers

MM optimized structures:  
cloroformio e *iso*-propilcloruro

In addition to being able to preserve highly labile species, they may serve as catalysts and accelerate reactions inside their inner cavity by either concentrating the reactants leading to higher effective concentrations or TS stabilization or by preorganising them inside the capsule.

They may create a micro-environment in which two encapsulated reactants are held together in a orientation that differs from their most reactive arrangement in solution (or gas phase) leading to products that are disfavoured in equivalent solution phase reactions.
