Liouville equation

- Classical system: N particles, Hamiltonian $H(\{\vec{q}_i, \vec{p}_i\})$, with $\vec{q}_i = (x_i, y_i, z_i)$ and $\vec{p}_i = (p_{x,i}, p_{y,i}, p_{z,i})$
- Equations of motion

$$\begin{aligned}\dot{\vec{q}}_i &= \frac{\partial H}{\partial \vec{p}_i} \\ \dot{\vec{p}}_i &= -\frac{\partial H}{\partial \vec{q}_i}\end{aligned}$$

- Density of particles at position $\vec{q}$ is proportional to the particle number

$$n(\vec{q}, t) = \sum_{i=1}^N \delta(\vec{q} - \vec{q}_i(t))$$

particle conservation $\int d\vec{q} n(\vec{q}, t) = N$

Liouville equation II

- Joint probability distribution function of finding the particle 1 at position $\vec{q}_1$ with momentum $\vec{p}_1$, ... particle i at position $\vec{q}_i$ with momentum $\vec{p}_i$, at time t

$$P(\{\vec{q}_i\}, \{\vec{p}_i\}, t) \propto \sum_i \delta(\vec{q}_i - \vec{q}_i(t)) \delta(\vec{p}_i - \vec{p}_i(t))$$

- Time evolution

$$\begin{aligned} \frac{\partial P(\{\vec{q}_i\}, \{\vec{p}_i\}, t)}{\partial t} = & - \left\{ \sum_i \frac{\partial}{\partial \vec{q}_i} [\delta(\vec{q}_i - \vec{q}_i(t))] \frac{\partial \vec{q}_i}{\partial t} \delta(\vec{p}_i - \vec{p}_i(t)) \right. \\ & \left. + \frac{\partial}{\partial \vec{p}_i} [\delta(\vec{p}_i - \vec{p}_i(t))] \frac{\partial \vec{p}_i}{\partial t} \delta(\vec{q}_i - \vec{q}_i(t)) \right\} \end{aligned}$$

- Plug the Hamilton's equations into the previous equation

$$\frac{\partial P(\{\vec{q}_i\}, \{\vec{p}_i\}, t)}{\partial t} = \sum_i - \frac{\partial}{\partial \vec{q}_i} \left[P(\{\vec{q}_i\}, \{\vec{p}_i\}, t) \frac{\partial H}{\partial \vec{p}_i} \right] + \frac{\partial}{\partial \vec{p}_i} \left[P(\{\vec{q}_i\}, \{\vec{p}_i\}, t) \frac{\partial H}{\partial \vec{q}_i} \right]$$

normalization is conserved $\int \prod_i d\vec{q}_i d\vec{p}_i P(\{\vec{q}_i\}, \{\vec{p}_i\}, t) = 1, \quad \forall t.$

Stochastic system

- Canonical ensemble ($T = \text{const.}$), prepare your system with any initial condition $P(\{\vec{q}_i\}, \{\vec{p}_i\}, 0)$
- at $t \rightarrow \infty$ you expect the system to be in equilibrium

$$P(\{\vec{q}_i\}, \{\vec{p}_i\}, t) = P_{eq}(\{\vec{q}_i\}, \{\vec{p}_i\}) = \frac{e^{-\beta H(\{\vec{q}_i, \vec{p}_i\})}}{Z}$$

- Extension of the Liouville equation

$$\frac{\partial P(\{\vec{q}_i\}, \{\vec{p}_i\}, t)}{\partial t} = \sum_i -\frac{\partial}{\partial \vec{q}_i} \left[P(\{\vec{q}_i\}, \{\vec{p}_i\}, t) \frac{\partial H}{\partial \vec{p}_i} \right] + \frac{\partial}{\partial \vec{p}_i} \left[P(\{\vec{q}_i\}, \{\vec{p}_i\}, t) \frac{\partial H}{\partial \vec{q}_i} \right] + \boxed{?}$$

Additional terms such that we obtain again the Liouville equation when we eliminate the source of stochasticity?

Brownian motion

A micron-sized particle in solution performs a *random walk*, as an effect of the large number of random collisions with the solvent molecules

Jean Baptiste Perrin, *Les Atomes* (1914)
mastic particle $r = 0.53 \mu\text{m}$, mesh size $3.2 \mu\text{m}$

Langevin equation

For a single particle in 1D

$$\begin{aligned}\dot{x} &= \frac{p}{m} \\ \dot{p} &= -U'(x) - \gamma \frac{p}{m} + \eta(t)\end{aligned}$$

$\eta(t)$ is called *Gaussian noise*

$$\langle \eta(t) \rangle = 0; \quad \langle \eta(t) \eta(t') \rangle = 2k_B T \gamma \delta(t - t')$$

Gaussian noise?

- The noise mimics the effect of the large number of random collisions with the solvent molecules
- Central limit theorem $\Rightarrow$ in a small interval δt

$$\mathcal{P}(\eta_t) = e^{-\delta t \frac{\eta_t^2}{4\gamma k_B T}} \sqrt{\frac{\delta t}{4\pi\gamma k_B T}} \Rightarrow \langle \eta_t \rangle = 0 \quad \text{AND} \quad \langle \eta_t \eta_{t'} \rangle = \frac{2\gamma k_B T}{\delta t} \delta_{t,t'}$$

with $\langle \eta_t \rangle = \int d\eta_t \eta_t \mathcal{P}(\eta_t)$, $\langle \eta_t \eta_{t'} \rangle = \int d\eta_t d\eta_{t'} \eta_t \eta_{t'} \mathcal{P}(\eta_t) \mathcal{P}(\eta_{t'})$, $t \neq t'$

Liouville eq. $\rightarrow$ Fokker-Planck eq.: quick and dirty

- $$\dot{x} = \frac{p}{m}; \quad \dot{p} = -U'(x) - \gamma \frac{p}{m} + \eta(t)$$

- $$\frac{\partial P(x, p, t)}{\partial t} = -\frac{\partial}{\partial x} \left[\frac{p}{m} P(x, p, t) \right] + \frac{\partial}{\partial p} \left[\left(U'(x) + \gamma \frac{p}{m} \right) P(x, p, t) \right] + \boxed{?}$$

- we want that $P_{eq}(\{\vec{q}_i\}, \{\vec{p}_i\}) = \frac{e^{-\beta H(\{\vec{q}_i, \vec{p}_i\})}}{Z}$, with $\partial_t P_{eq}(\{\vec{q}_i\}, \{\vec{p}_i\}) = 0$

- $$\begin{aligned} \frac{\partial P(x, p, t)}{\partial t} = & -\frac{\partial}{\partial x} \left[\frac{p}{m} P(x, p, t) \right] + \frac{\partial}{\partial p} \left[\left(U'(x) + \gamma \frac{p}{m} \right) P(x, p, t) \right] \\ & \boxed{+ \gamma k_B T \frac{\partial^2}{\partial p^2} P(x, p, t)} \end{aligned}$$

$P_{eq}(\{\vec{q}_i\}, \{\vec{p}_i\})$ is the stationary solution of the Fokker-Planck equation

Langevin eq. $\rightarrow$ Fokker-Planck eq.

- Let's consider a free particle $U(x) = 0 \Rightarrow \dot{p} = -\gamma p/m \Rightarrow$

$$p(t + \delta t) = p(t) - \delta t \gamma \frac{p(t)}{m} + \delta t \eta(t)$$

with no assumption on the noise variance

$$\mathcal{P}(\eta_t) = e^{-\delta t \frac{\eta_t^2}{2A}} \sqrt{\frac{\delta t}{2\pi A}} \Rightarrow \langle \eta_t \rangle = 0 \quad \text{AND} \quad \langle \eta_t \eta_{t'} \rangle = \frac{A}{\delta t} \delta_{t,t'} (*)$$

- Conditional probability of finding momentum p' given that you start from p

$$P(p', t + \delta t | p, t) = \langle \delta(p' - p(t + \delta t)) \rangle_{\text{noise}}$$

where $\langle \dots \rangle_{\text{noise}}$ is an average over $\mathcal{P}(\eta_t)$

- Let's define $\epsilon = \delta t(-\gamma p/m + \eta(t))$, and $p = p(t)$, we have

$$\delta(p' - p - \epsilon) \simeq \delta(p' - p) + \epsilon \frac{\partial}{\partial p} [\delta(p' - p)] + \frac{\epsilon^2}{2} \frac{\partial^2}{\partial p^2} [\delta(p' - p)]$$

Langevin eq. $\rightarrow$ Fokker-Planck eq. II

- Consider eq. (*) in the previous slide, and keep the terms up to the first order in δt (notice $\eta(t) \sim \sqrt{A/\delta t}$)

$$P(p', t + \delta t | p, t) = \langle \delta(p' - p - \epsilon) \rangle_{\text{noise}} = \left[1 - \delta t \gamma \frac{p}{m} \frac{\partial}{\partial p} + \delta t \frac{A}{2} \frac{\partial^2}{\partial p^2} \right] \delta(p' - p)$$

- Use $P(p', t + \delta t) = \int dp P(p', t + \delta t | p, t) P(p, t)$

$$\frac{\partial P(p, t)}{\partial t} = \frac{\partial}{\partial p} \left[\gamma \frac{p}{m} P(p, t) \right] + \frac{A}{2} \frac{\partial^2}{\partial p^2} P(p, t)$$

- We want $P(p, t \rightarrow \infty) = P_{eq}(p) = \exp[-\beta p^2/2m] / Z$, with $\partial_t P_{eq}(p) = 0 \Rightarrow$

$A = 2\gamma k_B T$

Fluctuation-dissipation relation: the noise (A) and the friction force ($-\gamma p/m$) have the same physical origin

Fokker-Planck $\rightarrow$ Smoluchowski eq.

- in the Langevin eq.

$$m\dot{v} = -U'(x) - \gamma v + \eta(t)$$

let's assume that the relaxation time $\tau = m/\gamma \ll 1$ is much smaller than any natural time scale associated with the motion in the potential $U(x)$:
overdamped regime

Neglect the inertial contribution $m\dot{v}/\gamma$

- The Langevin equation becomes

$$\dot{x} = -\Gamma U'(x) + \tilde{\eta}(t), \quad \text{with } \Gamma = 1/\gamma, \quad \langle \tilde{\eta}_t \tilde{\eta}_{t'} \rangle = 2\Gamma k_B T \delta(t - t')$$

- With a procedure similar to the one described above one obtains the Smoluchowski equation

$$\frac{\partial P(x, t)}{\partial t} = \Gamma \frac{\partial}{\partial x} [U'(x) P(x, t)] + \Gamma k_B T \frac{\partial^2}{\partial x^2} P(x, t)$$

Einstein relation

Smoluchowski equation with $U(x) = 0$

$$\frac{\partial P(x, t)}{\partial t} = \Gamma k_B T \frac{\partial^2}{\partial x^2} P(x, t)$$

with stationary solution $P_{st}(x) = \exp(-x^2/(4Dt))/\sqrt{4\pi Dt}$

$$D = \Gamma k_B T$$

$$\langle \Delta x^2 \rangle_t = 2Dt$$

Generalized Brownian motion

Evolution of an observable: $m(x, p)$ takes values m

$$P_{eq}(m) = \int dx dp \delta(m(x, p) - m) \frac{e^{-\beta H(x, p)}}{Z} \equiv \frac{e^{-\beta \mathcal{F}(m)}}{Z}$$

A SDE for m

$$\frac{dm}{dt} = \mathcal{V}(m) + \eta_m(t),$$

assumptions:

- m varies over time scales which are longer than those for $\eta_m(t)$
- $\eta_m(t)$ is the result of many independent processes
 $\Rightarrow \eta_m$ Gaussian with $\langle \eta_m \eta'_m \rangle = 2\lambda \delta(t - t')$
- m is independent of the instantaneous value of m (this requirement can be relaxed)

Generalized Brownian motion (cont.)

Write a FP equation

$$\frac{\partial P(m, t)}{\partial t} = -\partial_m [\mathcal{V}(m)P(m, t)] + \lambda \frac{\partial^2}{\partial m^2} P(m, t)$$

and require $P_{eq}(m)$ to be the steady state solution

$$\Rightarrow \mathcal{V}(m) = -\frac{\lambda}{k_B T} \partial_m \mathcal{F}(m)$$

and defining $\Gamma = \lambda/k_B T$ we obtain

$$\frac{dm}{dt} = -\Gamma \partial_m \mathcal{F}(m) + \eta_m(t), \quad \langle \eta_m \eta'_m \rangle = 2k_B T \Gamma \delta(t - t')$$

Construction of a field theory

Fields $\phi_{\mathbf{l}}$ defined on N sites of a d -dimensional regular lattice with position $\mathbf{x}_{\mathbf{l}}$

$$H(\{\phi_{\mathbf{l}}\}) = \sum_{\mathbf{l}} G(\phi_{\mathbf{l}}) + \frac{1}{2} \sum_{\mathbf{l}, \mathbf{l}'} K_{\mathbf{l}, \mathbf{l}'} (\phi_{\mathbf{l}} - \phi_{\mathbf{l}'})^2$$

with $G(\phi)$ a power series expansion about $\phi = 0$ and $K_{\mathbf{l}, \mathbf{l}'}$ a finite range coupling matrix.

The partition function and the (overdamped) Langevin equation are well defined

$$Z = \int \prod_{\mathbf{l}} d\phi_{\mathbf{l}} e^{-\beta H(\{\phi_{\mathbf{l}}\})}$$
$$\frac{d\phi_{\mathbf{l}'}}{dt} = -\frac{\partial H(\{\phi_{\mathbf{l}}\})}{\partial \phi_{\mathbf{l}'}} + \eta_{\mathbf{l}'}(t), \quad \langle \eta_{\mathbf{l}}(t) \eta_{\mathbf{l}'}(t') \rangle = 2k_B T \delta_{\mathbf{l}, \mathbf{l}'} \delta(t - t')$$

Construction of a field theory (cont.)

continuum limit

- volume per lattice site $\mathfrak{w} \rightarrow 0$ and keep the total volume $V = N\mathfrak{w}$ constant
- $\mathbf{x}_1 \rightarrow \mathbf{x}$ continuous variable
- $\sum_1 \rightarrow \int d\mathbf{x}/\mathfrak{w}$ (d-dim)

- $$\sum_1 G(\phi_1) \rightarrow \int d\mathbf{x} g[\phi(x)], \quad g = G/\mathfrak{w}$$

- $$\frac{1}{2} \sum_{1,1'} K_{1,1'} (\phi_1 - \phi_{1'})^2 \rightarrow \frac{1}{2} \int d\mathbf{x} k (\nabla \phi(\mathbf{x}))^2, \quad k = \frac{1}{d\mathfrak{w}} \sum_1 \mathbf{x}_1^2 K_{1,0}$$

$$H[\phi(\mathbf{x})] = \int d\mathbf{x}' g[\phi(\mathbf{x}')] + \frac{1}{2} k (\nabla \phi(\mathbf{x}'))^2$$

$$Z = \int \mathcal{D}\phi(\mathbf{x}) e^{-\beta H[\phi(\mathbf{x})]}$$

Time dependent Landau-Ginzburg equation

$$\begin{aligned}\frac{d\phi(\mathbf{x})}{dt} &= -\frac{\delta H[\phi(\mathbf{x})]}{\delta\phi(\mathbf{x})} + \eta(\mathbf{x}, t), \\ \langle \eta(\mathbf{x}, t) \eta(\mathbf{x}', t') \rangle &= 2k_B T \delta(\mathbf{x} - \mathbf{x}') \delta(t - t')\end{aligned}$$

Taking, e.g., $g[\phi(\mathbf{x})] = r\phi^2(\mathbf{x})/2 + u\phi^4(\mathbf{x})/4$ one obtains

$$\begin{aligned}H[\phi(\mathbf{x})] &= \int d\mathbf{x}' \frac{r}{2} \phi^2(\mathbf{x}') + \frac{u}{4} \phi^4(\mathbf{x}') + \frac{1}{2} k (\nabla \phi(\mathbf{x}'))^2 \\ \frac{d\phi(\mathbf{x})}{dt} &= -r\phi(\mathbf{x}) - u\phi(\mathbf{x})^3 + k \nabla^2 \phi(\mathbf{x}') + \eta(\mathbf{x}, t)\end{aligned}$$
