

# Polymers: Introduction

- Polymer: High molecular weight molecule made up of a small repeat unit (monomer).
  - A-A
- Monomer: Low molecular weight compound that can be connected together to give a polymer
- Oligomer: Short polymer chain
- Copolymer: polymer made up of 2 or more monomers
  - Random copolymer: A-B-B-A-A-B-A-B-A-B-B-B-A-A-B
  - Alternating copolymer: A-B-A-B-A-B-A-B-A-B-A-B-A-B
  - Block copolymer: A-A-A-A-A-A-A-A-B-B-B-B-B-B-B-B

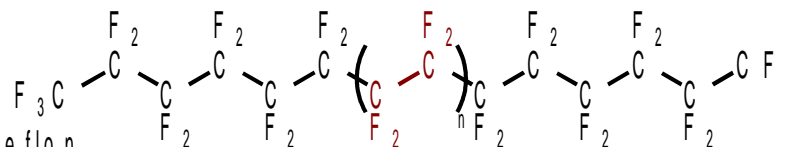

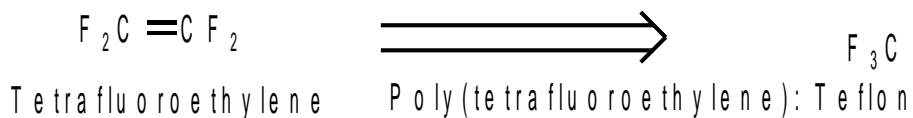

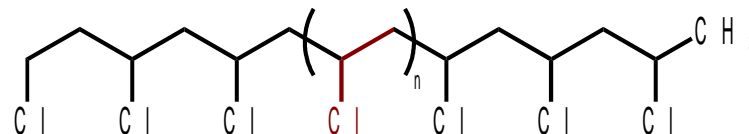

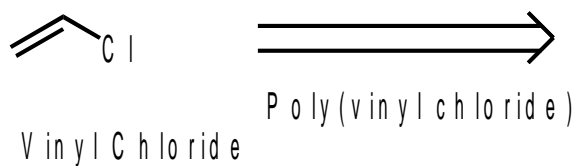

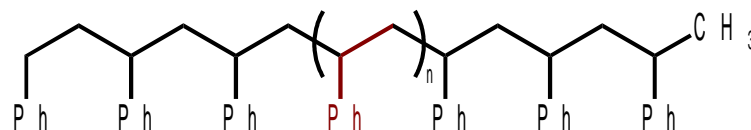

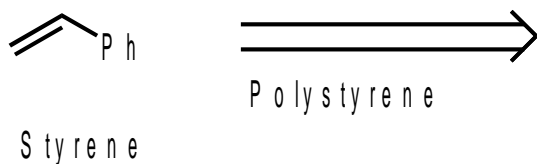

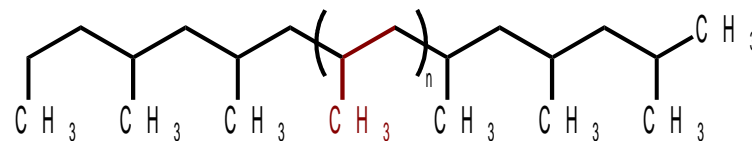

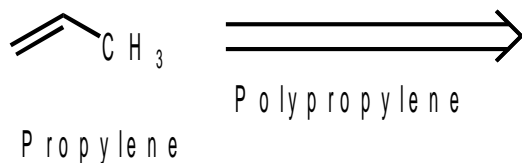

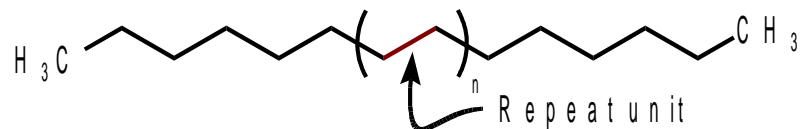

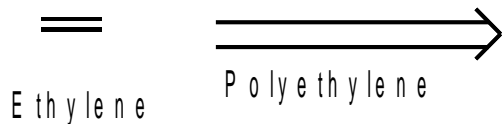

# Types of Polymers

- Polymer Classifications
  - Thermoset: cross-linked polymer that cannot be melted (tires, rubber bands)
  - Thermoplastic: Melttable plastic
  - Elastomers: Polymers that stretch and then return to their original form: often thermoset polymers
  - Thermoplastic elastomers: Elastic polymers that can be melted (soles of tennis shoes)
- Polymer Families
  - Polyolefins: made from olefin (alkene) monomers
  - Polyesters, Amides, Urethanes, etc.: monomers linked by ester, amide, urethane or other functional groups
  - Natural Polymers: Polysaccharides, DNA, proteins

## Monomer

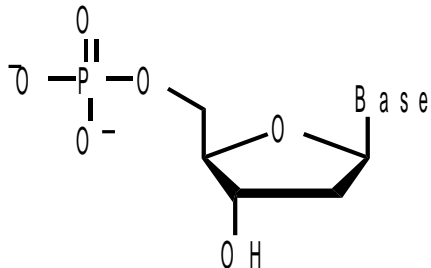

Polyisoprene:  
Natural rubber

Poly( $\beta$ -D-glycoside):  
cellulose

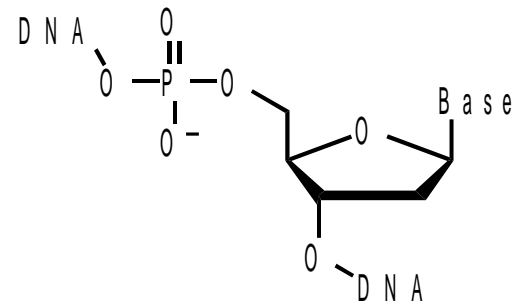

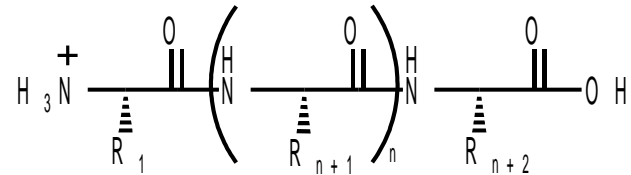

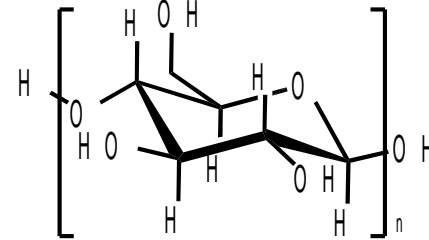

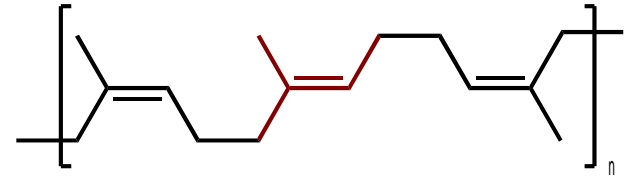

Polyamino acid:  
protein

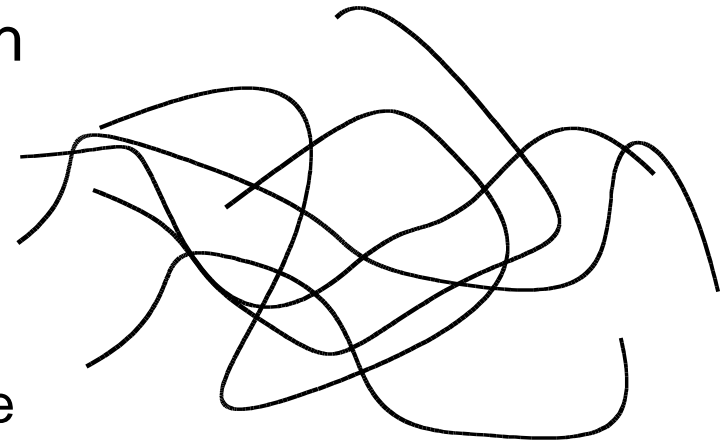

oligonucleic acid  
DNA

## Polymer

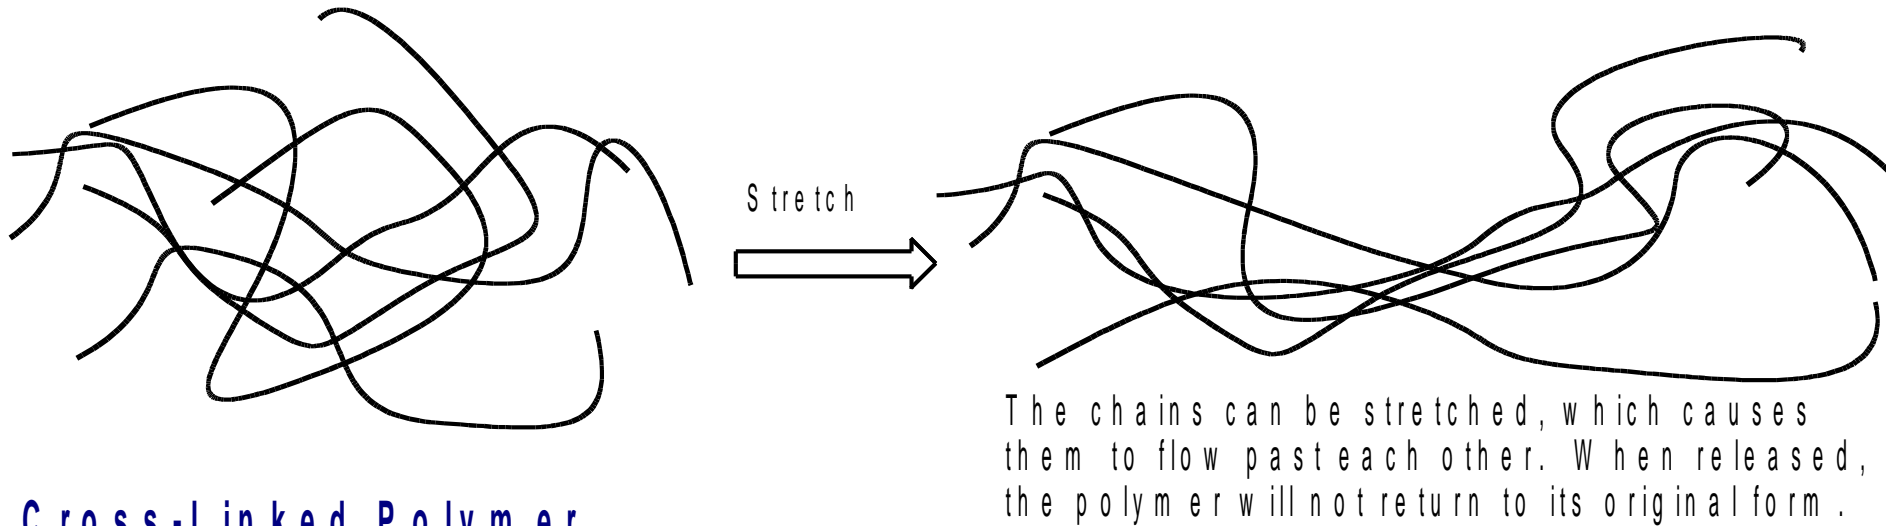

# What Makes Polymers Unique?

- Really big molecules (macromolecules) like polymers have very different properties than small molecules
  - Chain entanglement: Long polymer chains get entangled with each other.
    - When the polymer is melted, the chains can flow past each other.
    - Below the melting point, the chains can move, but only slowly. Thus the plastic is flexible, but cannot be easily stretched.
    - Below the glass transition point, the chains become locked and the polymer is rigid

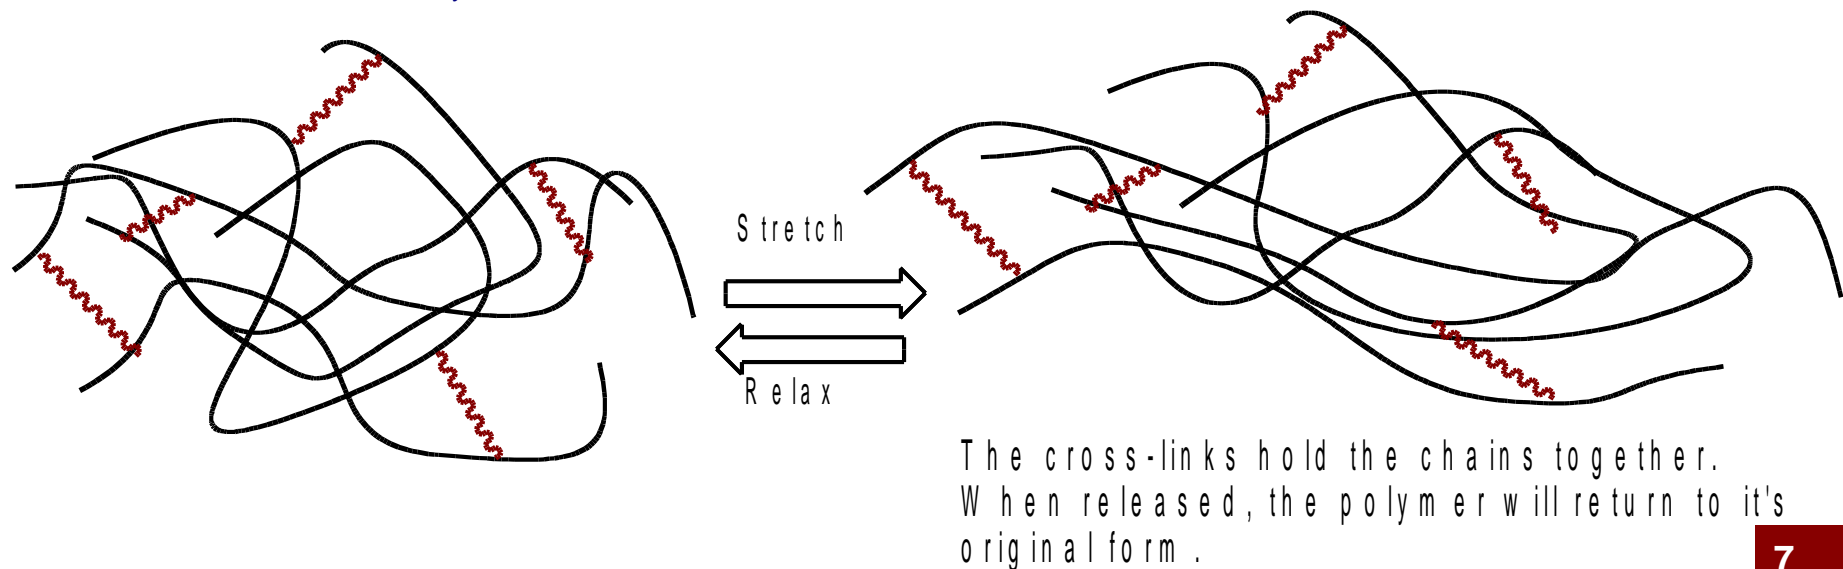

# Physical Properties

## Linear Polymer

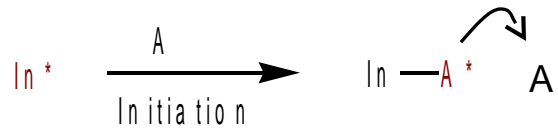

## Cross-Linked Polymer

# Polymer Synthesis

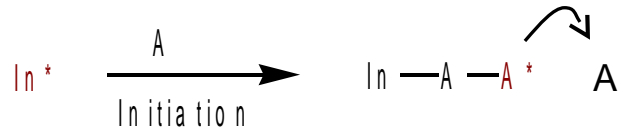

- There are two major classes of polymer formation mechanisms
  - Addition polymerization: The polymer grows by sequential addition of monomers to a reactive site
    - Chain growth is linear
    - Maximum molecular weight is obtained early in the reaction
  - Step-Growth polymerization: Monomers react together to make small oligomers. Small oligomers make bigger ones, and big oligomers react to give polymers.
    - Chain growth is exponential
    - Maximum molecular weight is obtained late in the reaction

# Addition Polymerization

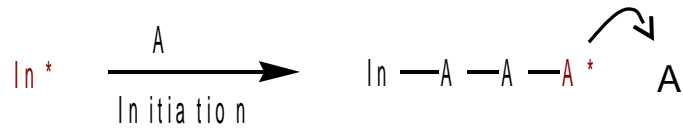

# Addition Polymerization

Propagation

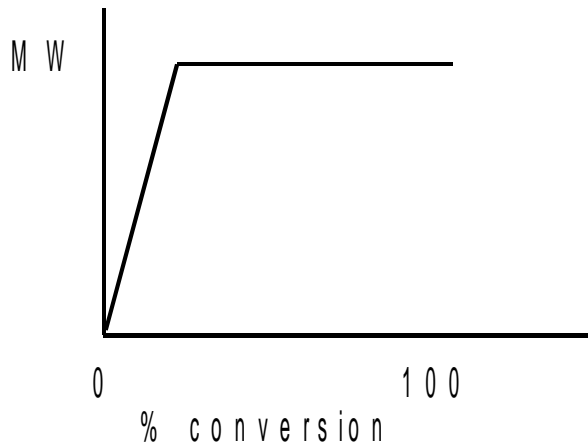

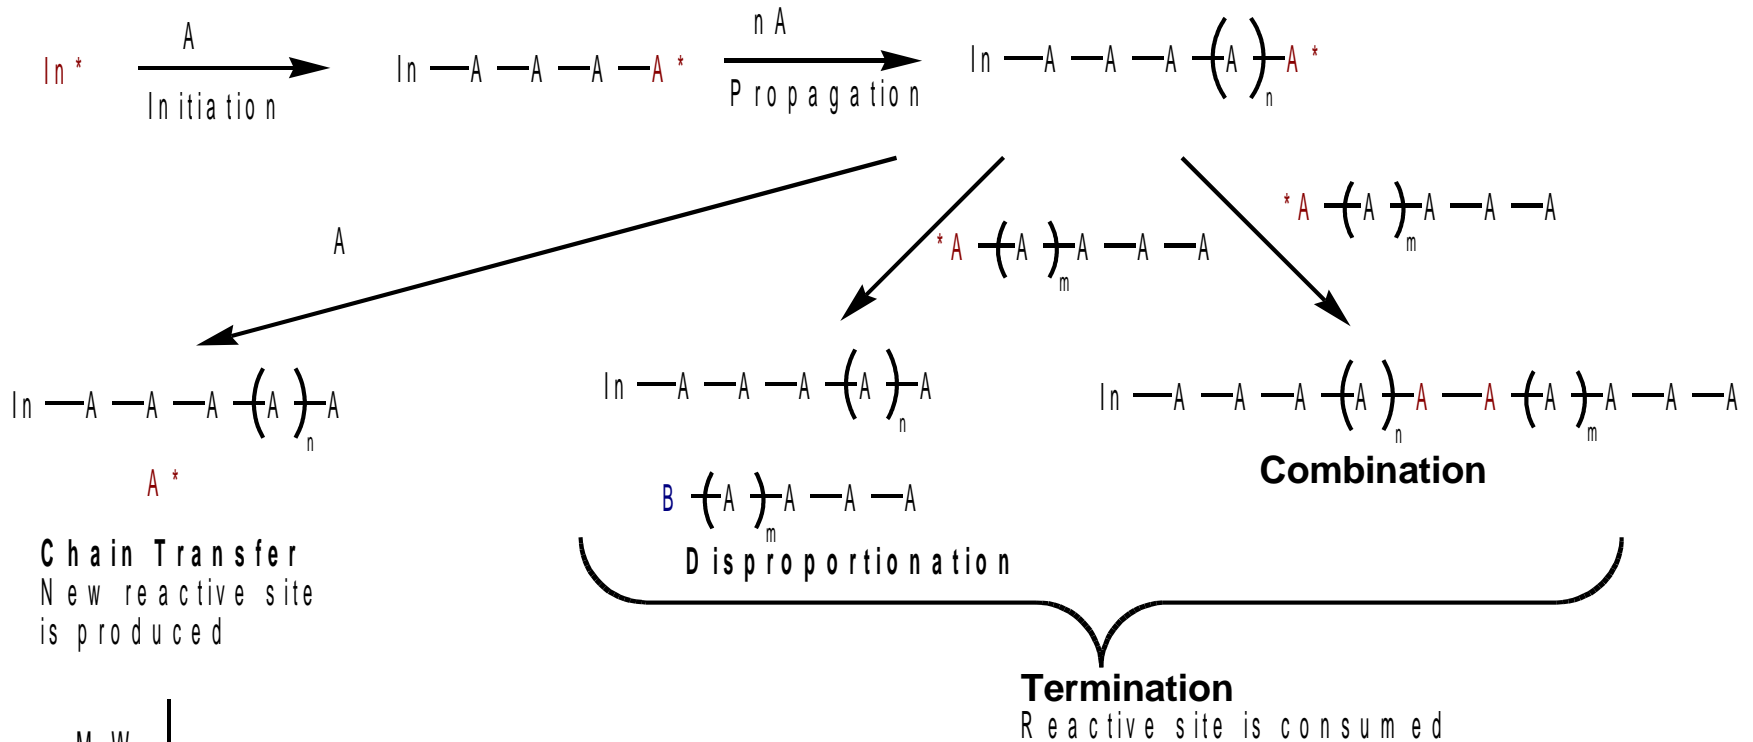

# Addition Polymerization

Propagation

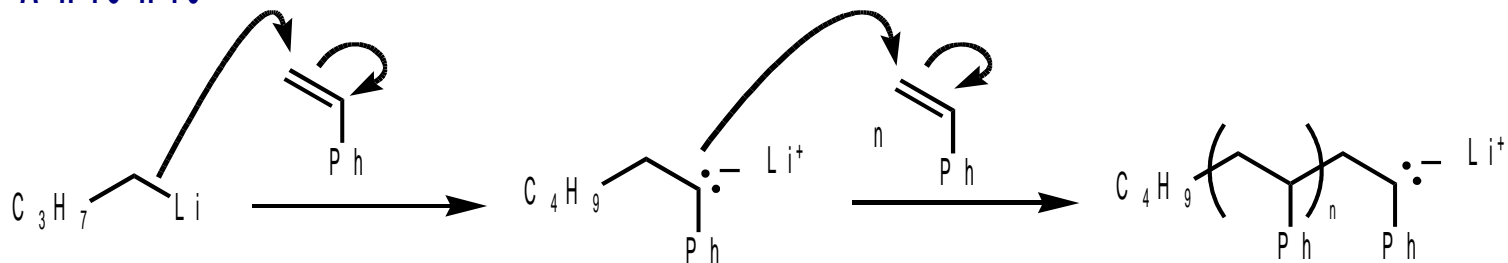

# Addition Polymerization

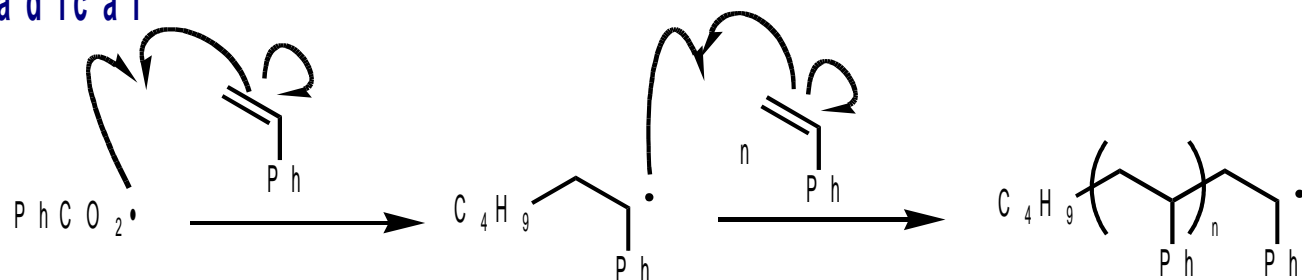

$$M W \propto \frac{k_{\text{propagation}}}{k_{\text{termination}}}$$

# Types of Addition Polymerizations

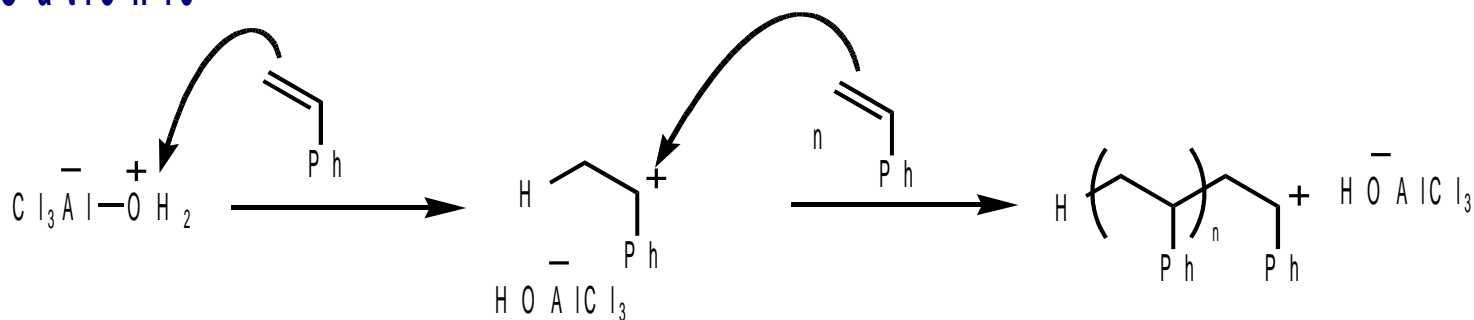

## Anionic

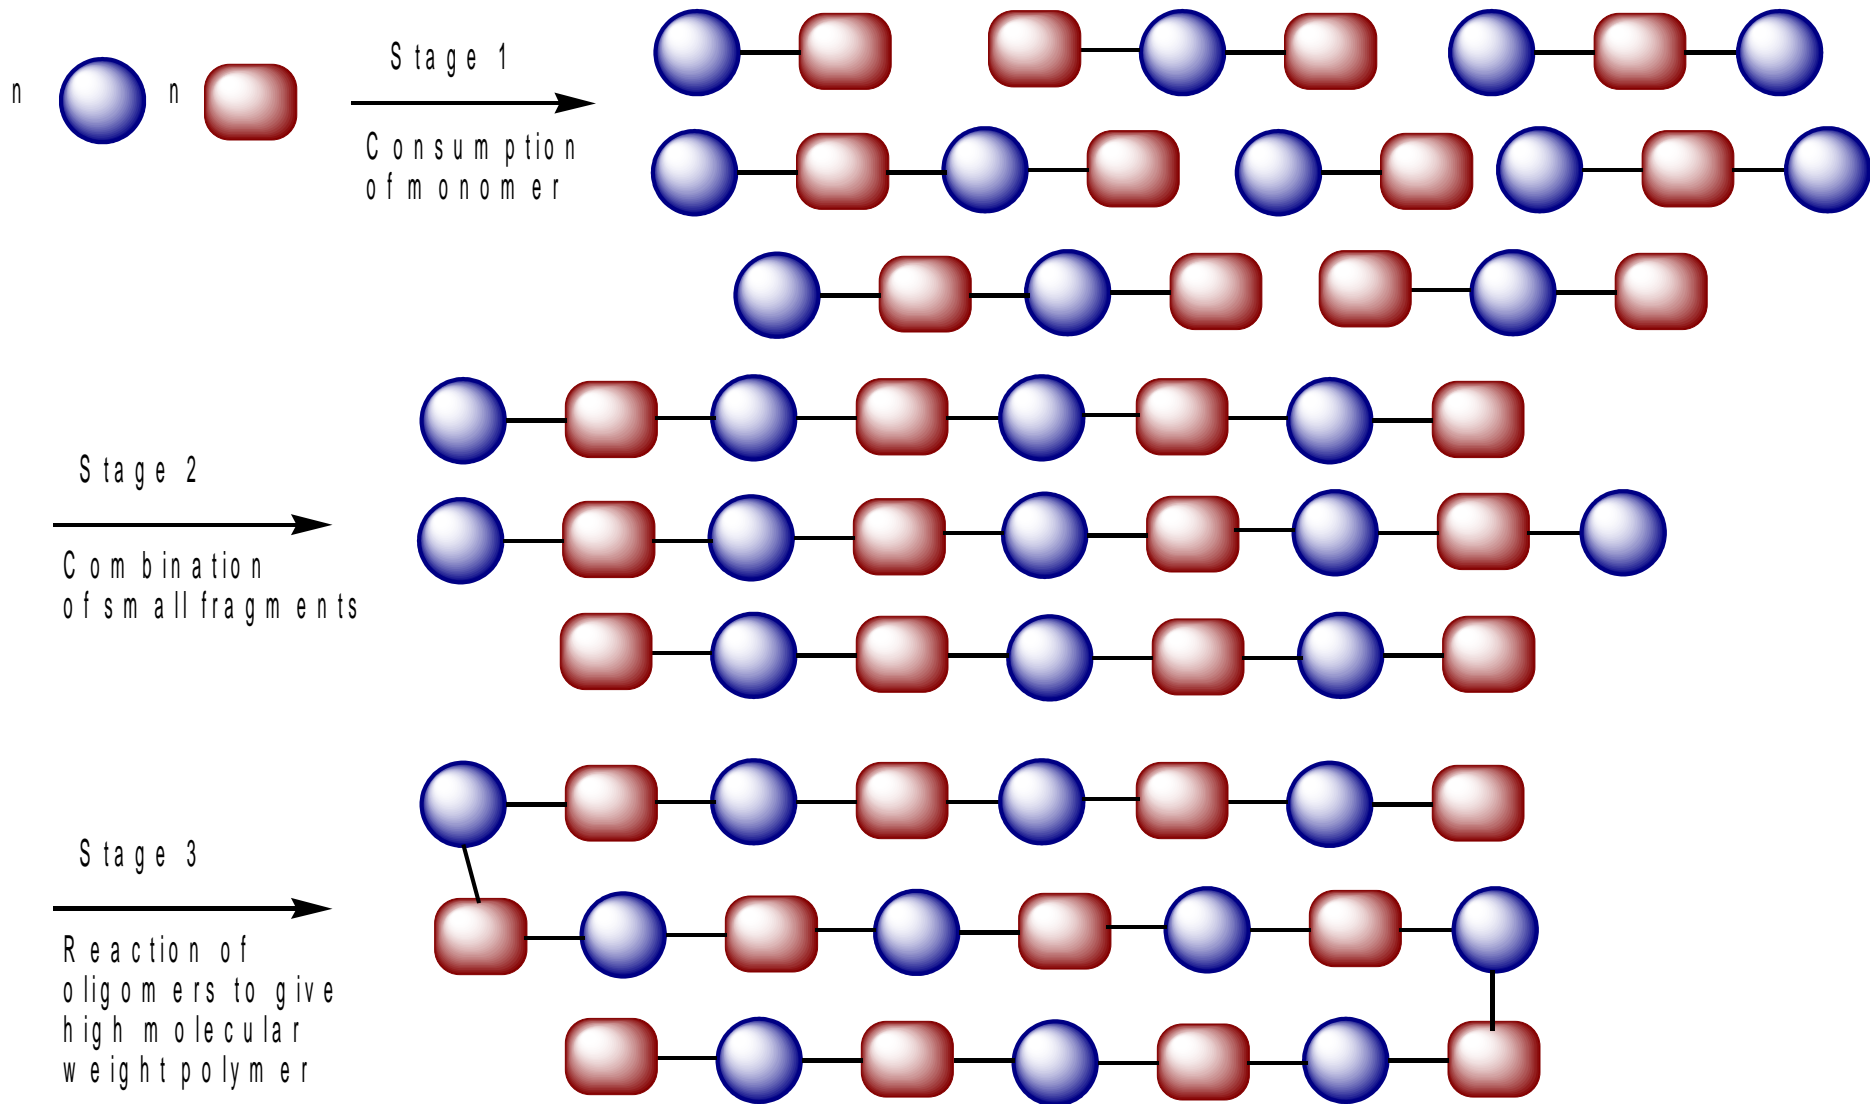

## Radical

## Cationic

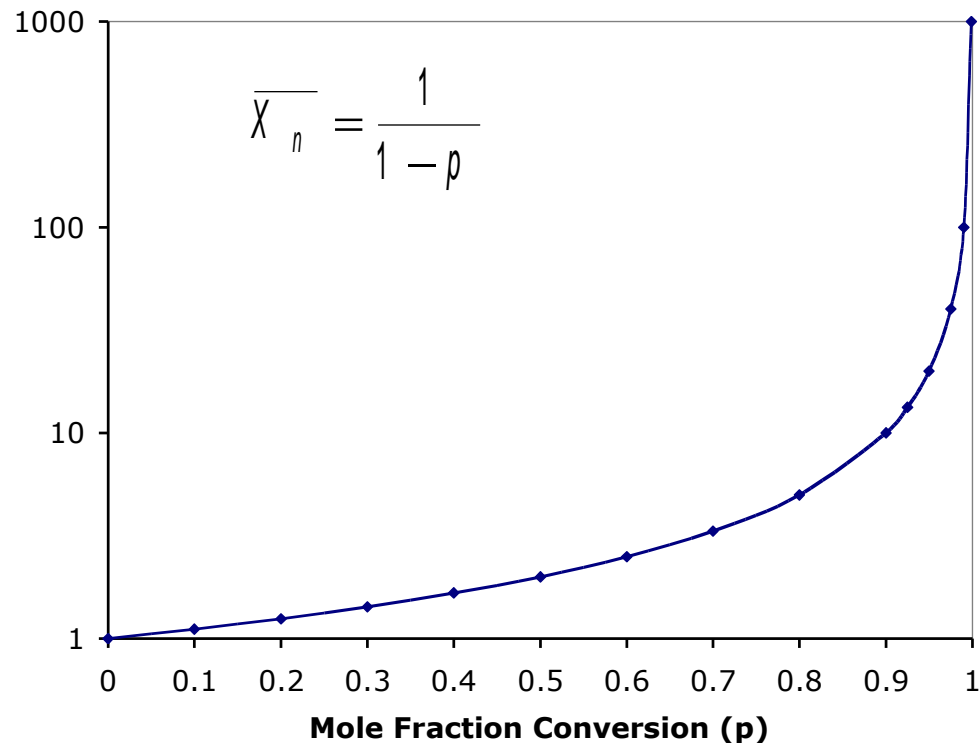

# Step-Growth Polymerization

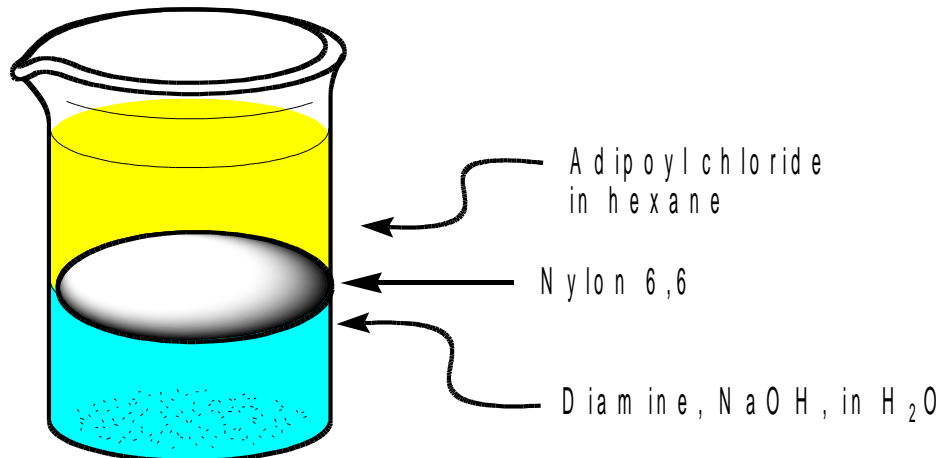

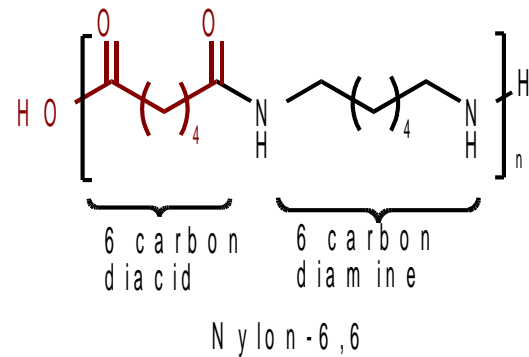

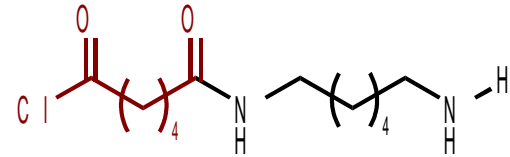

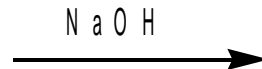

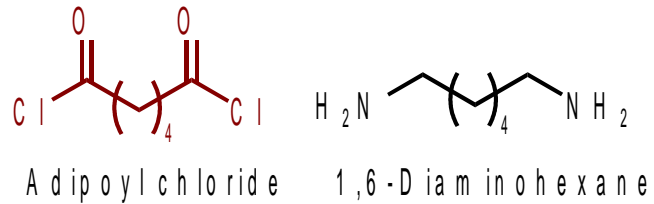

# Step-Growth Polymerization

- Because high polymer does not form until the end of the reaction, high molecular weight polymer is not obtained unless high conversion of monomer is achieved.

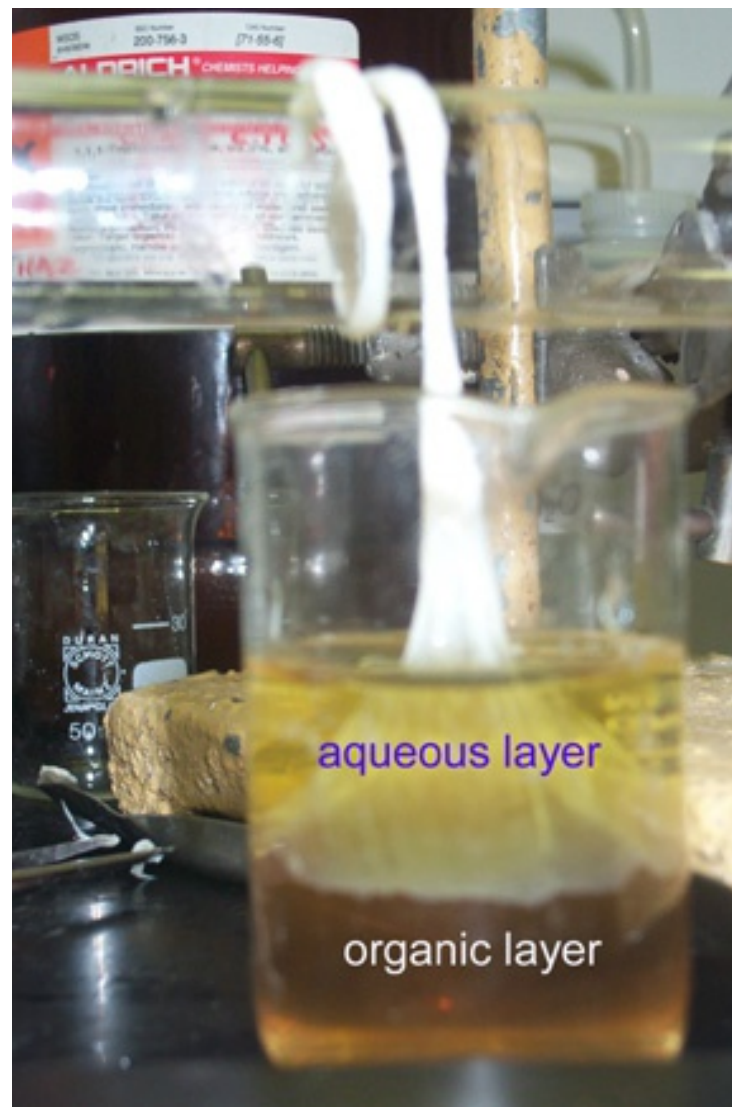

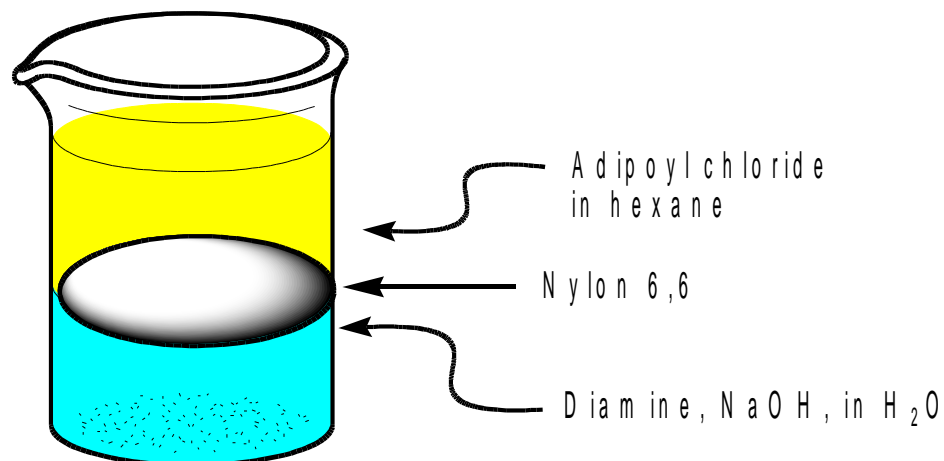

$\overline{X}_n$  = Degree of polymerization  
 $p$  = mole fraction monomer conversion

# Nylon-6,6

# Nylon-6,6

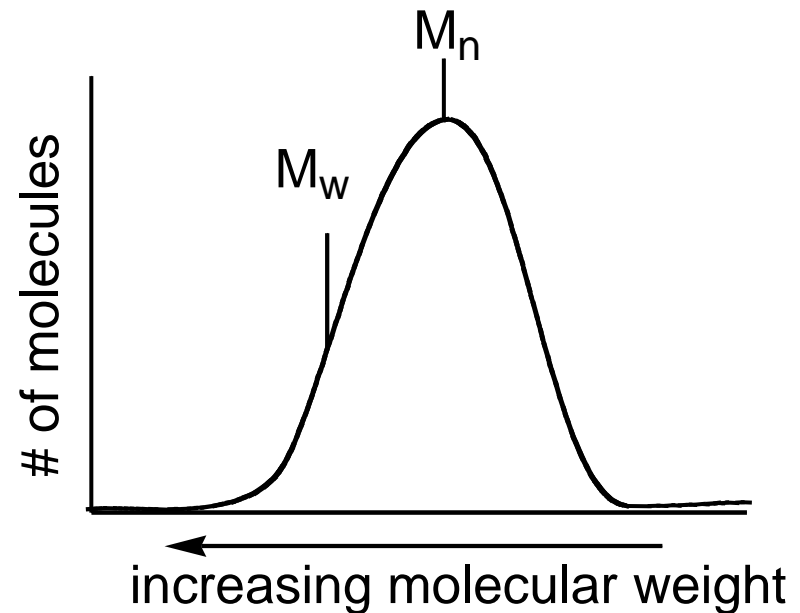

Since the reactants are in different phases, they can only react at the phase boundary. Once a layer of polymer forms, no more reaction occurs. Removing the polymer allows more reaction to occur.

# Molecular Weight of Polymers

Unlike small molecules, polymers are typically a mixture of differently sized molecules. Only an average molecular weight can be defined.

- Measuring molecular weight
  - Size exclusion chromatography
  - Viscosity
- Measurements of average molecular weight (M.W.)
  - Number average M.W. ( $M_n$ ): Total weight of all chains divided by # of chains
  - Weight average M.W. ( $M_w$ ): Weighted average. Always larger than  $M_n$

# What the Weights Mean

$M_n$ : This gives you the true average weight

Let's say you had the following polymer sample:

2 chains:	1,000,000 Dalton	2,000,000
5 chains:	700,000 Dalton	3,500,000
10 chains:	400,000 Dalton	4,000,000
4 chains:	100,000 Dalton	400,000
2 chains:	50,000 Dalton	<u>100,000</u>
		10,000,000

$$10,000,000/23 = 435,000 \text{ Dalton}$$

$$1 \text{ Dalton} = 1 \text{ g/Na}$$

# Weight Average Molecular Weight

$M_w$ : Since most of the polymer mass is in the heavier fractions, this gives the average molecular weight of the most abundant polymer fraction by mass.

$$\frac{2,000,000}{10,000,000} = 0.20 \times 1,000,000 = 200,000$$

$$\frac{3,500,000}{10,000,000} = 0.35 \times 700,000 = 245,000$$

$$\frac{4,000,000}{10,000,000} = 0.40 \times 400,000 = 160,000$$

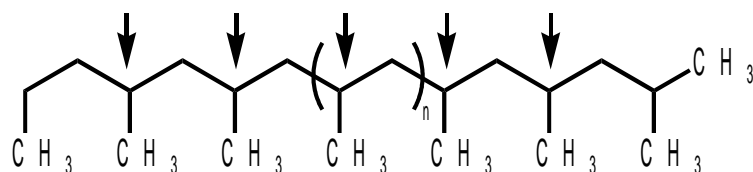

$$\frac{400,000}{10,000,000} = 0.04 \times 100,000 = 4,000$$

$$\frac{100,000}{10,000,000} = 0.01 \times 50,000 = 500$$

$$\text{Total} = 609,500$$

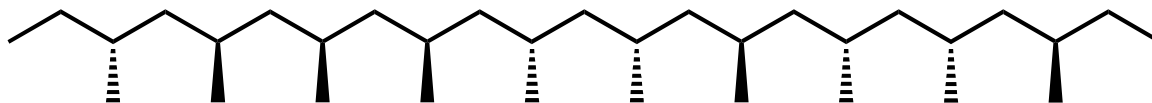

# Polymer Microstructure

Polyolefins with side chains have stereocenters on every other carbon

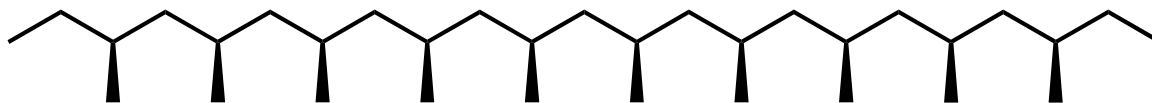

With so many stereocenters, the stereochemistry can be complex. There are three main stereochemical classifications for polymers.

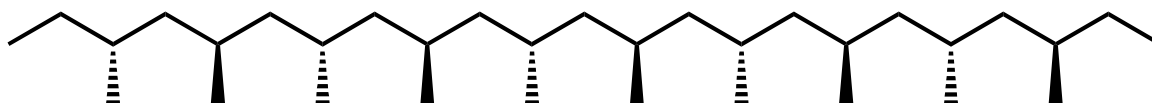

**A t a c t i c:** r a n d o m   o r i e n t a t i o n

**I s o t a c t i c:** A l l   s t e r e o c e n t e r s   h a v e   s a m e   o r i e n t a t i o n

**S y n d i o t a c t i c:** A l t e r n a t i n g   s t e r e o c h e m i s t r y

# Why is this important?

- Tacticity affects the physical properties
  - Atactic polymers will generally be amorphous, soft, flexible materials
  - Isotactic and syndiotactic polymers will be more crystalline, thus harder and less flexible
- Polypropylene (PP) is a good example
  - Atactic PP is a low melting, gummy material
  - Isoatactic PP is high melting ( $176^{\circ}$ ), crystalline, tough material that is industrially useful
  - Syndiotactic PP has similar properties, but is harder to synthesize
